In 1900-1 the number of pupils entered upon the registers of the common schools—that is, the public elementary and the public secondary schools—was 15,603,451, or 20.20 per cent of the total population and 71.26 per cent of the persons of "school age." The total population of Scotland is only a little more than a third of this. For these pupils 430,004 teachers were employed, of which number 123,941 or 28.8 per cent were men. The women teachers in the common schools numbered 306,063. The teachers, if brought together in 1901 would have outnumbered the population of Sheffield, the women alone more than equaling the population of New Orleans. No fewer than 249,969 buildings were in use for common school purposes. The aggregate value of public school property was nearly \$577,000,000 (\$576,963,089).

The average length of the annual school session was 144.2 days, an increase since 1870 of 12 days. In some States the length of the annual school session is very much above this average. It rises, for example, to 191 days in Rhode Island, 185 in Massachusetts, 183 in New Jersey, 177 in New York, 165.02 in California, 160 in Iowa, 163 in Michigan, and 169 in Wisconsin. The shortest average annual session is in North Carolina (76.1 days) and in Alabama (78.3). Taking the entire educational resources of the United States into consideration, each individual of the population would receive school instruction for 5.14 years of 200 days each. Since 1870 this has increased from 3.36 years, and since 1880 from 3.96 years, of 200 days each.

The average monthly salary of men teachers in the common schools was \$47.55 in 1900-1; that of the women teachers was \$39.17. The total receipts for common school purposes in 1900-1 were almost \$235,000,000 (\$234,967,919), of which vast sum 4.2 per cent was income from permanent funds, 16.4 per cent was raised by State school tax, 68.6 per cent by local (county, municipal, or school district) tax, and 10.8 came from other sources. The common school expenditure per capita of population was \$2.93; for each pupil, it averaged \$21.14. Teachers' and superintendents' salaries absorb 63.2 per cent (\$142,776,168) of the expenditure for com-

mon schools. The commissioner of education believes the normal standard of enrollment in private educational institutions to be about 15 per cent of the total enrollment, though often decreased in periods of commercial and financial depression.

Illiteracy.—Illiteracy in the United States can hardly be compared fairly with that in European countries because of the fact that an overwhelming proportion of the illiterates are found among the negroes and among the immigrants who continue to pour into the country in large numbers. The 12th census of the United States, taken in 1900, showed that the percentage of illiterates to the whole population was 10.7, a decrease of 2.6 per cent since the census of 1890. But the percentage of illiterates among the native white population (74.4 per cent of the whole population) was only 4.6 per cent of those of 10 years of age or older. Among the foreign-born white population (13.4 per cent of the whole), the percentage of illiteracy was 12.9 per cent, and among the colored population (11.6 per cent of the whole) it was 44.5. That is, considerably over one half of the whole number of illiterates in the United States were colored. Only in Alabama, Arkansas, Georgia, Indian Territory, Kentucky, Louisiana, New Mexico, North Carolina, South Carolina, Tennessee, and Virginia was the percentage of illiteracy among the native white population greater than 10. This percentage fell below 2 in Washington (0.5), Montana (0.6), Nevada (0.6), South Dakota (0.6), Wyoming (0.7), Connecticut (0.8), District of Columbia (0.8), Massachusetts (0.8), Minnesota (0.8), Nebraska (0.8), Oregon (0.8), Utah (0.8), Alaska (0.9), Idaho (0.9), North Dakota (0.9), California (1.0), Iowa (1.2), New York (1.2), Kansas (1.3), Wisconsin (1.3), New Hampshire (1.5), Michigan (1.7), New Jersey (1.7), and Rhode Island (1.8).

Education and Crime.—It is not infrequently charged by those who have but a superficial knowledge of the facts, or who are disposed to weaken the force of the argument for State education, that one effect of the system of public education in the United States has been to increase the proportion of criminals, particularly those whose crime is against property. The facts in refutation of this charge are simple and indisputable. In the first place, it must be remembered that communities maintaining schools have higher standards as to what is lawful than communities without the civilization which the presence of a school system indicates, and that, therefore, more acts are held to be criminal and more crimes are detected and punished in a community of the former sort than in one of the latter. A greater number of arrests may indicate better police administration instead of any increase in crime. Again, where records have been carefully kept, it appears that the illiterate portion of the population furnishes from six to eight times its proper proportion of criminals. This was established for a large area by an extensive investigation carried on by the bureau of education in 1870.

The history of the past 50 years in the State of Massachusetts is alone a conclusive answer to the contention that education begets crime. In 1850 the jails and prisons of that State held

EDUCATION IN THE UNITED STATES

8,761 persons, while in 1855 the number had increased to three times as many (26,651). On the surface, therefore, crime had greatly increased. But analysis of the crimes shows that serious offenses had fallen off 40 per cent during this period, while the vigilance with which minor misdemeanors were followed up had produced the great apparent increase in crime. While drunkenness had greatly fallen off in proportion to the population, yet commitments for drunkenness alone multiplied from 3,341 in 1850 to 18,701 in 1885. The commitments for crimes other than drunkenness were 1 to every 183 of the population in 1850 and 1 to every 244 of the population in 1885. In other words, as has been pointed out, persons and property had become safer, while drunkenness had become more dangerous—to the drunkard.

The American people are convinced that their public school system has justified the argument of Daniel Webster, made in 1821: "For the purpose of public instruction," he said, "we hold every man subject to taxation in proportion to his property, and we look not to the question whether he himself have or have not children to be benefited by the education for which he pays; we regard it as a wise and liberal system of police, by which property, and life, and the peace of society are secured. We seek to prevent, in some measure, the extension of the penal code by inspiring a salutary and conservative principle of virtue and of knowledge in an early age. We hope to excite a feeling of respectability and a sense of character by enlarging the capacities and increasing the sphere of intellectual enjoyment. . . . Knowing that our government rests directly upon the public will, that we may preserve it we endeavor to give a safe and proper direction to the public will. We do not, indeed, expect all men to be philosophers or statesmen; but we confidently trust . . . that by the diffusion of general knowledge, and good and virtuous sentiments, the political fabric may be secure as well against open violence and overthrow as against the slow but sure undermining of licentiousness."

Education and Industry.—Where the public school term in the United States is longest, there the average productive capacity of the citizen is greatest. This can hardly be a coincidence. When the man of science finds such a coincidence as this in his test tube or balance, he proclaims it a scientific discovery proved by inductive evidence. According to a calculation made a few years ago, when the proportion between the school period in Massachusetts and the school period in the whole United States was as 70 to 43, it was found that the proportion between the productive capacity of each individual in Massachusetts and that of each individual in the whole United States, was as 66 to 37. Education, 70 to 43; productivity, 66 to 37. On the basis of 306 working days in Massachusetts, and on the basis of a population something over 2,000,000, this meant that every citizen of Massachusetts—man, woman, infant in arms—was to be credited with a productive capacity every year of \$88.75 more than the average for the United States as a whole. Or to put it in the most striking fashion, it meant that the excess of productive capacity for the State of Massachusetts in one year was \$200,000,000, or about

20 times the cost of maintaining the public schools. If the State of North Carolina, for example, could bring it about through education that every individual's productive capacity was increased 10 cents a day—that is, just one third the Massachusetts excess—for 306 working days, estimating the present population roughly at 1,900,000, the State would be better off in the next calendar year to the amount of more than \$58,000,000. North Carolina now spends less than \$1,000,000 a year for public education.

Public Secondary Education.—The number of public secondary schools, high schools, in the United States in 1900-1 was 6,318, employing 21,778 teachers and enrolling 541,730 pupils. The rapid increase of these schools, the flexibility of their programme of studies and the growing value of the training which they offer, are among the most significant educational facts of the last two decades. The rate of increase of secondary school pupils between the 11th and the 12th census was greater than the rate of increase of the population. It is noteworthy, too, that nearly 50 per cent of the whole number of secondary school pupils are studying Latin. In the public high schools the number equals 50.45 per cent.

Between 1890 and 1896, while the number of students in private secondary schools increased 12 per cent, the number of students in public secondary schools increased 87 per cent. Further, since 1893-4 the number of pupils in private secondary schools has steadily declined, the decrease in 1900-1 being 6.12 per cent as compared with the previous year; while the increase in public secondary schools was 5.34 per cent.

Local Influence of the College.—The number of universities and colleges in the United States—473, excluding those for women only—is very large. Many of these institutions, small and weak, ill-equipped and ill-endowed, are frequently criticised severely for endeavoring to continue the struggle for existence. This criticism is, in part, justifiable, but it ought not to be forgotten that almost every college exerts a helpful influence upon the life of its locality. The fact is frequently overlooked that all American colleges depend for their students in large measure upon their own neighborhood. Few draw from the nation at large, and these few draw only a small proportion of their students from beyond the confines of their own State or the limits of their own section of the country. In some cases the percentage of students who are residents of the State in which they attend college is from about 95 per cent to nearly 100 per cent.

American Universities.—The development of universities in the United States has taken place during the present generation. The name "university" is, in America, no proper index to the character and work of the institution which bears it. Prof. Perry has set out illustrations of this fact with great clearness. Nevertheless, the distinctions between secondary school, college and university are more widely recognized each year and it is not too much to hope that, in course of time, the various institutions will adopt the names which properly belong to each.

The definition of a university which I have suggested elsewhere is this: "An institution,

EDUCATION

where students, adequately trained by previous study of the liberal arts and sciences, are led into special fields of learning and research by teachers of high excellence and originality; and where, by the agency of museums, laboratories, and publications, knowledge is conserved, advanced, and disseminated." In this sense there are at least half a dozen American universities now in existence, and as many more in the process of making. These universities are markedly different from those of France, Germany, and Great Britain, but they respond in a most complete way to the educational needs of the American people, and they are playing an increasingly important part in the advancement of knowledge and the development of its applications to problems of government, of industry, and of commerce. The administrators of American universities have studied carefully the experience of European nations, and they have applied the result of that experience, wherever possible, in the solution of their own problems.

Literature of Education.—The variety and value of American contributions to the literature of education are worthy of notice. About 250 periodical publications of one type or another are devoted mainly to education. A few of these rank with the leading educational journals of the world. Perhaps the publications of the National Educational Association, a voluntary organization of teachers of every grade, are the most characteristic American contributions. They include not only the invaluable series of annual 'Proceedings,' containing papers and discussions by the leaders of American education for a generation, but reports upon particular subjects the investigation of which has been undertaken from time to time by special committees. Among the subjects so reported upon are these: Secondary School Studies, Organization of Elementary Education, Rural Schools, College Entrance Requirements, Relation of Public Libraries to Public Schools, and Normal Schools.

The most valuable official publications are these: the annual reports, issued since 1868, by the United States commissioner of education, those since 1889 being particularly noteworthy; the reports issued by Horace Mann as secretary of the State board of education of Massachusetts, 1838-49; the 12 volumes of reports issued by William T. Harris, as superintendent of the public schools of St. Louis, Mo., 1867-79; and the annual reports of Charles W. Eliot as president of Harvard University, 1871-99. The annual reports of State and city superintendents of schools are a storehouse of information and often contain elaborate discussions of educational theory and practice.

Private Aid to Education.—One fact in American education is certainly unique. That is the vast sum given in aid or endowment of education by individuals. It recalls the best traditions of the princes and churchmen of the Middle Ages, but is on a vastly larger scale. For some time past the income of Harvard University from this source has been nearly or quite \$1,000,000 annually. In 1898-9 the total amount of gifts to Harvard University for purposes of general or special endowment was \$1,383,460.77, and for immediate use \$161,368.90. In 1900-1 Chicago University received \$2,575,492

and Washington University (St. Louis) \$3,450,000. Columbia University received in one decade \$6,736,482 in money and in land. An unofficial estimate of the amount given by individuals during the year 1899 for universities, colleges, schools, and libraries was over \$70,000,000. The total amount of benefactions reported for 1900 by the various institutions for higher education was \$18,040,413. The tendency which these colossal figures indicate is one of the most fortunate and most hopeful in American life. The makers and holders of great fortunes are pouring out from their excess for the development of the higher life and greater productive capacity of the people. The religious bodies, in particular the Roman Catholic Church, are doing the same thing upon a very large scale. The conviction that education is fundamental to democratic civilization is perhaps the most widespread among the American people. Public funds and private wealth are alike given unstintingly in support of it.

Study of Education.—Education, conceived as a social institution, is now being studied in the United States more widely and more energetically than ever before. The chairs of education in the great universities are the natural leaders in this movement. It is carried on also in normal schools, in teachers' training classes, and in countless voluntary associations and clubs in every part of the country. Problems of organization and administration, of educational theory, of practical procedure in teaching, of child nature, of hygiene and sanitation, are engaging attention everywhere. Herein lies the promise of great advances in the future. Enthusiasm earnestness and scientific method are all applied to the study of education in a way which makes it certain that the results will be fruitful. The future of democracy is bound up with the future of education. See EDUCATIONAL ORGANIZATION AND ADMINISTRATION; STUDY OF EDUCATION.

Education, Agricultural. See AGRICULTURAL EDUCATION.

Education, Board of, United States. Established 1867 independently this was made a bureau of the interior department in 1868. Its function is to collect statistics of educational conditions and progress throughout the Union, and diffuse information on school systems and methods of teaching. Up to 1900 it had published 360 books and pamphlets. The first commissioner for whom in recognition of his immense and gratuitous educational work the office was created, was Henry Barnard of Connecticut; the present one (since 1889) is William T. Harris, originally of Connecticut.

Education, Commercial. See COMMERCIAL EDUCATION.

Education, Compulsory. This subject embraces compulsory attendance on the part of the child, and compulsory preparation on the part of the teacher. History shows that from the earliest ages, laws making education compulsory, under certain conditions, have been in existence. The Greeks, Romans, and others of the oldest civilized nations, or forms of government, had most rigorous laws regarding military education; as the Spartans going so far as to

EDUCATION

regulate the food and the dress of the male children, in order to make the bodies of the youths have greater power of endurance, and thus fit them for being defenders and protectors of the state. The nature of the education depended upon the environment as much as upon hereditary laws and customs. As conditions changed it was easy to pass from laws making military education compulsory to laws making compulsory the study of other subjects deemed essential to the welfare of the state.

There has never in any nation been unanimity of opinion regarding the right of the state to make and enforce compulsory education laws. The question in some form or degree has always presented itself: "Does the child belong to the parents or to the state?" Another question, co-ordinate with the one mentioned, has also given rise to much discussion among the friends and opponents of state compulsory education laws, is: "Shall the child be educated for the benefit of the parents or the state, or in such a manner as shall best develop his own natural powers regardless of the relation to parents or the state?" Another question which underlies both is: "What is the law by which the Creator works; and what are the laws He has imposed upon all things created?" These questions are complicated and far-reaching; but their solutions are essential for the line of argument to be followed in determining the needs and rights for making education, in some form, compulsory; and also in deciding who shall make the laws and by whom and how they shall be executed.

Compulsory education laws usually necessitate free schools; although in the United States the order of development has been the reverse of that followed in most European countries. In the United States generally the free school came first, and for the sake of the development of the individual, with society in the background, and the race not a factor. The compulsory legislation followed the free school. In European countries generally the compulsory laws came first, and the free school (not an eleemosynary school) followed. Under the old condition of things, the youth had to learn something to make him of value to the state, and in time the school in which he must learn had to be provided for him. The evolution from the camp, and the rush bed of the Spartan, and from the training for the athlete and the warrior to the elementary schools and colleges of to-day, is not difficult to follow, as mighty changes made needs and wants of nations different from the past. Prussia, Saxony, Württemberg, Baden, and other places made education compulsory early in the general movement. Later all of Germany, Holland, and other European countries followed. In 1876 a compulsory attendance law was enacted for certain schools in Great Britain and Ireland; but until 1880 "the matter of making by-laws compelling school attendance was optional with district boards, or school attendance committees. The law passed in 1880 empowered the educational department to make compulsory by-laws for all school districts where local authorities failed to take such action. Parents and employers violating the law are punished by fine and imprisonment."

In Switzerland attendance at elementary schools is compulsory in every canton. The

length of time attendance is required varies from six to nine years, in the different cantons. In the cantons of Bern and Solothurn girls are required to attend industrial and domestic science schools for one year after completing the regular elementary course. In the canton of Thurgovie girls must attend eight years day school, and additional two years singing and industrial school. In all the cantons of Switzerland, instruction in knitting, sewing, darning, embroidering, etc., is given to girls, and although the law does not make those studies compulsory in all places, they are all studied.

In the United States, the agitation regarding compulsory education laws began almost with the establishment of the school, and in nearly every State, the law regulating the establishment and support of schools by some form of general taxation was followed by the compulsory education law. As the "child labor" question became prominent, compulsory education forced itself more and more upon public attention. In 1647 Massachusetts made a law regarding the compulsory attendance of children at school, Kent (Vol. II., p. 196) says: "The compulsory system upon parents and masters to teach their children and servants to read, was enforced by fine in Massachusetts, by act of 1642, and in Plymouth colony laws in 1671." In the Massachusetts records mention is made of some "people of the town of Dedham who were indicted, tried, convicted, and fined for neglecting to keep and support a grammar school."

For various reasons, not the least of which were the changes made by the Revolutionary War, the 17th century compulsory education laws of Massachusetts became dead laws. At the session of the Massachusetts legislature in 1852, a general compulsory education law was passed, the first law of the kind passed in America after the 17th century laws which had become obsolete and ineffective. This Massachusetts law of 1852 applied to children between the ages of 8 and 14 years, and covered only 12 weeks of each school year, only six of which had to be consecutive. The penalty inflicted upon the parent or guardian neglecting to have a child comply with the law, did not exceed a fine of \$20, and no imprisonment. The child was not obliged to attend a public school, "but must be furnished with the means of education for a like period of time," or the child might be entirely exempt from attendance if he had "already acquired those branches of learning which are taught in common schools." Defective children were exempt from obedience to this law. To the town treasurer was given the authority to execute this law; but like the 17th century law, its enforcement was neglected, and its efficiency was never really tested.

The modern movement toward compulsory education in the United States has been influenced by all the causes which existed in the past, and in addition the new phases of the "child labor" and street education questions. Riis says: "Three fourths of all juvenile delinquency in New York is the result of truancy and the street life of children." New York State, early in the movement passed laws compelling attendance at school, but the penalty was not sufficient to make the breaking or neglecting of the law a serious matter. Under the revised statutes with duly authorized truant

EDUCATION

officers, and truant schools, the law is practically enforced. The child may attend any school or may be instructed by any one except in two cases. When the pupil desires to secure a scholarship in Cornell University attendance at a public school the six school months previous is necessary to make him eligible. To be eligible for a position as teacher in any city in the State of New York attendance and graduation from a State normal school or training class, or three years' successful experience is required. The law thus specifies the schools which the pupil must attend in the cases mentioned.

In 32 States and Territories of the United States there are laws regulating the compulsory school attendance of minors. The child is compelled to attend the whole school year or a specified number of weeks. The age limits vary from 6, 7, and 8, on the one side, to 14, 15, and 16 on the other, except in Wyoming where all under 21 years must attend school 12 weeks in each year. The penalties on parents and guardians for neglect to comply with the law, are in fines from \$2 to \$200 and imprisonment and in some cases forfeiture of public school money by school districts not enforcing the law.

The truancy laws are becoming more rigid in the United States. (See TRUANT SCHOOL.) The laws regarding the compulsory preparation of the teacher have kept pace with the laws regarding compulsory attendance. See TEACHERS, PROFESSIONAL TRAINING OF; COLLEGES FOR TEACHERS.

Consult: Reports of U. S. Commissioner of Education; Reports of State Superintendents of the United States; Reports of State Departments of different European countries.

Education, Elementary. In all the schools of the United States, public and private, elementary, secondary and higher, there were enrolled in the year 1899-1900 about 17,500,000 pupils. The actual average attendance for each pupil in the public or common schools did not exceed 98 days, although the average length of the school session was 1,446 days.

Out of this entire number deduct the pupils of private and parochial schools of all kinds, elementary, secondary, higher, and schools for art, industry and business, for defective classes and Indians, there remain over 15,300,000 for the public school enrolment, or nearly 90 per cent of the whole. The great growth of public schools in the last 30 years may be gathered from a 60 per cent increase in the cost of common schools, owing to better apparatus and more commodious school buildings, but especially to longer terms and higher salaries to teachers. The effect of the great increase of railways in the same period is to extend the suburbs of cities and vastly increase the urban population. The rural schools in sparsely settled districts still continue their old practice of holding a winter school with a session of 60 to 80 days only, and taught by the makeshift teacher who works at some other employment for two thirds of the year. The school year of ideal length should be about 200 days, or five days per week for 40 weeks, that is, nine and one half months. In the early days of city schools the attempt was made to hold a session of over 46 weeks in length, allowing only six weeks or less for three short vacations. But experience of their advantage to the pupil has led to the increase of the holidays to nearly double the former amount.

The average schooling, it appears from the above showing, amounts to enough to secure for each person a little more than one half of an elementary school course of eight years,— enough to enable the future citizen to read the newspaper, to write fairly well, to count, add, subtract, multiply and divide, and use the simplest fractions. In addition he acquires a little geographical knowledge, so important to enable him to understand the references or allusions in his daily newspaper to places of interest in other parts of the world. But the multiplicity of cheap books and periodicals makes the life of the average citizen a continuation of school to some extent. The transformation of an illiterate population into a population that reads the daily newspaper, and perforce thinks on national and international interests, is thus far the greatest good accomplished by the free public school system of the United States. That this general prevalence of elementary education is accompanied by a comparative neglect of the secondary and higher courses of study is evident from the fact that out of the number of pupils enrolled more than 95 in every 100 are pursuing elementary studies; less than 4 in 100 are in secondary studies in high schools, academies and other institutions; only 1 in 100 (13 in 1,000) is in a college or a school for higher studies.

In considering the reasons for the increase of the length of the term of the elementary school and its adoption of a graded course of study, one comes upon the most important item of improvement that belongs to the recent history of education, namely, the introduction of professionally trained teachers. The first normal school established in the United States was founded at Lexington, Mass., in 1839. The number of public normal schools supported by the State or municipal governments has increased since that year to nearly 200, and there is about an equal number of private normal schools. In 1880 there were 240 normal school students in each 1,000,000 of inhabitants; in 1897 there were 936, or nearly four times as many in each 1,000,000. The professionally educated teacher finds his place in the graded schools, and he continues to improve in skill and efficiency for many years. The advantage of the professionally educated teacher above others is to be found in the fact that he has been trained to observe methods and devices of instruction. The normal school graduate, too, other things being equal, has a better idea than other teachers of the educational value of a branch of study. He knows what points are essential, and what are accidental and subsidiary. He therefore makes his pupils thoroughly acquainted with those strategical positions, and shows him how to conquer all the rest through these.

As it would appear from the statistics given, the rural districts are precluded by their short school terms from securing professional teachers. The corps of teachers in a highly favored city will be able to claim a large percentage of its rank and file as graduates of its municipal training schools—perhaps 50 to 60 per cent; but the cities and villages as a whole in their graded schools cannot as yet show an average of more than one teacher in four who has received the diploma of a normal school. Another important advantage has been named as belonging to the schools of the village or city. They are graded schools, and have a regular

EDUCATION

course of study, uniformity of text-books, and a proper classification of pupils. In the small rural schools some 20 to 50 pupils are brought together under one teacher. Their ages vary from 4 years to 20, and their degree of advancement ranges from beginners up to those who have attended school for 10 or 12 winters, and are now attempting Latin and algebra. It often happens that there is no uniformity of text-books, except perhaps in the spelling-book and reader, each pupil bringing such arithmetic, geography or grammar as his family at home happens to possess. This was the case in the old-time district school—such as existed in 1790, when 29 out of 30 of the population lived in rural districts, and 50 years later when only 1 in 12 lived in a city. As the railroad has caused villages to grow into cities, so it has virtually moved into the city a vast population living near railway stations in the country by giving them the morning newspaper and rapid transportation. In 1890 one third of the population was living in cities of not less than 8,000 inhabitants. But the suburban populations made urban by the railroad swell the city population to one half of the whole nation. Hence the great change now taking place in methods of building school-houses and in organizing schools.

With the growth from the rural to the urban condition of population the method of "individual instruction" has been supplanted by class instruction, which prevails in village and city schools. The individual did not get much instruction under the old plan, for the simple reason that his teacher had only 5 or 10 minutes to examine him on his daily work. In the properly graded school each teacher has two classes, and hears one recite while the other learns a new lesson. Each class is composed of 20 to 30 pupils of nearly the same qualifications as regards the degree of progress made in their studies, and all pupils learn more by a class recitation than by an individual recitation, for in the class each can see the lesson reflected in the minds of his fellow pupils, and understand his teacher's views much better when drawn out in the form of a running commentary on the mistakes of the duller or more indolent pupils. The possibilities of a class recitation are, therefore, very great for efficient instruction in the hands of a teacher who understands his business. From beginning to end, for 30 minutes, the class recitation is a vigorous training in critical alertness. The pupil afterward commences the preparation of his next lesson from the book with what are called new "apperceptive" powers, for he finds himself noticing and comprehending many statements and a still greater number of implications of meaning in his lesson that before had not been seen or even suspected.

It is presupposed that the chief work of the pupil in school is the mastery of text-books containing systematic treatises giving the elements of branches of learning taught in the schools. The evil of memorizing words without understanding their meaning or verifying the statements made in the text-book is incident to this method and is perhaps the most widely prevalent defect in teaching to be found in the schools of the United States. The oral method of Germany escapes this evil almost entirely, but encounters another. The pupil taught by the oral method exclusively is apt to lack power to master

the printed page and get out of it the full meaning; he needs the teacher's aid to explain the technical phrases and careful definitions. The American method of text-book instruction throws the child upon the printed page and holds him responsible for its mastery. In the hands of a trained teacher the good of the method is obtained and the evil avoided. The pupil is taught to assume a critical attitude toward the statements of the book and to test and verify them, or else disprove them by appeal to other authorities, or to actual experiments.

In the graded school the pupil is held responsible for his work in a way that is impossible in the rural school of sparsely settled districts. Hence the method of investigation, as above described, is found in the city schools rather than in the rural schools. Where the ungraded school makes some attempt at classification of pupils it is obliged to unite into one class say of arithmetic, grammar, or geography, pupils of very different degrees of progress. The consequence is that the most advanced pupils have not enough work assigned them, being held back to the standard of the average. It must be admitted that in many village schools just adopting the system of grading, this evil of holding back the bright pupils and of over-pressure on the dull ones exists, and furnishes just occasion for the criticism which is made against the so-called "machine" character of the American public school. I have dwelt on this somewhat technical matter because of its importance in understanding the most noteworthy improvements in progress in the schools of the United States. Briefly, the population is rapidly becoming urban, the schools are becoming "graded." Here there is division of labor on the part of teachers, one taking only classes just beginning to learn to read and write, another taking the pupils in a higher grade. The inevitable consequence of such division of labor is increase of skill. The complaint urged against the machine character of the modern school is made quite as often against good schools as against poor ones. But the critical-probing method of conducting a recitation is certainly not machine-like in its effects. It arouses in the most powerful manner the activity of the pupil to think and observe for himself. It is admitted that about 50 per cent of the teachers actually teaching in the schools of villages and cities use this poor method. But it is certain that their proportion in the corps of teachers is diminishing, thanks to the two causes already alluded to: first, the multiplication of professional schools for the training of teachers; and second, the employment of educational experts as supervisors of schools.

Another phase of the modern school that more than anything else gives it the appearance of a machine is its discipline, or method of organization and government. In the graded school with 300 to 800 pupils order and discipline are necessary down to the last particular, for the safety of the pupils as well as for the accomplishment of the ends for which the school exists. There must be regularity and punctuality, silence and conformity to order, in coming and going. These things seem at first to be so much waste of energy. But the moment the question of moral training comes to be investigated, the superiority of the education given in the large school is manifest. The pupil is taught to be regular and punctual in his attendance on school

EDUCATION

and in all his movements, not for the sake of the school alone, but for all his relations to his fellow men. He learns to respect the serious business of others. In moving to and fro by a sort of military concert and precision he acquires the impulse to behave in an orderly manner, to stay in his own place and not get in the way of others. Hence he prepares for concerted action, — another important lesson in citizenship, leaving entirely out of account its military significance. With the increase of cities and the growth of great industrial combinations this discipline in the virtues that lie at the basis of concerted action is not merely important, but essential. Precision, accuracy, implicit obedience to the head or directive power, are necessary for the safety of others and for the production of any positive results. The rural school does not fit its pupils for an age of productive industry and emancipation from drudgery by means of machinery, but the city school performs this so well that it reminds some people unpleasantly of a machine.

In the matter of school discipline again the graded school has an advantage over the school of the rural district. A corps of teachers can secure good behavior more efficiently than a single teacher. The system, and its very "mechanism," help this result. In many cities of the largest size in the United States, corporal punishment is seldom resorted to, or is entirely dispensed with, and the discipline of the school seems to improve as a result. The adoption of a plan of building giving each class-teacher a room to herself, in which pupils to the number of 50 or so prepare their lessons under the eye of the same teacher that conducted their recitations makes it possible to manage a school with little or no corporal punishment. That the public schools of cities have worked great and favorable changes to the advantage of civil order cannot be doubted. They have generally broken up the feuds that used to prevail between the people of different precincts. Learning to live without quarreling with school-fellows is an efficient preparation for an orderly and peaceful life with one's neighbors. It is a stronger moral force than the rural school because of its superior training in the social habits named — regularity, punctuality, orderly concerted action and self-restraint.

Even in colonial times as far back as 1642 a compulsory law was enacted in Massachusetts inflicting penalties on parents for the neglect of education.

In the Connecticut colony in 1650 the Massachusetts law was adopted. Amendments were adopted in 1805 and 1821. By a law of 1813 manufacturing establishments were compelled to see that "the children in their employ were taught to read, write and cipher, and that attention was paid to their morals." In 1842 a penalty was attached to a similar law which forbade "the employment of children under the age of 15 years unless they had been instructed at school at last 3 months of the 12 preceding." At the present 30 States, one Territory and the District of Columbia have laws making education compulsory, generally at a public or approved private school. Sixteen States and one Territory do not make education compulsory, although all of these have fully organized systems of schools free to every child of school age of whatever condition. The most general period of required attendance

at school is from 8 to 14 years of age, as is the case in Vermont, District of Columbia, West Virginia, Indiana, Michigan, North Dakota, South Dakota, Nebraska, Kansas, Montana, Colorado, Utah, Nevada, Idaho, Oregon and California. It begins likewise at 8, but is extended to 15 in Maine and Washington, and is from 8 to 16 in New Hampshire, Connecticut, New York, Pennsylvania, Minnesota and New Mexico. The child is required to begin attendance at the earlier age of 7, and continue to 12 in New Jersey, to 13 in Wisconsin, to 14 in Massachusetts, Kentucky and Illinois; to 15 in Rhode Island, and to 16 in Wyoming. In Massachusetts and Connecticut the child is required to attend the full time that the schools are in session; in New York and Rhode Island, also, the full term, with certain exceptions in favor of children employed to work. In Pennsylvania the attendance is required for 70 per cent of the full term; in California for 66 2-3 per cent; for 20 weeks annually in Vermont, New Jersey, Ohio and Utah; 16 weeks annually in Maine, West Virginia, Illinois, Michigan and Nevada; 12 weeks annually in New Hampshire, District of Columbia, Indiana, Wisconsin, Kansas, North Dakota, South Dakota, Nebraska, New Mexico, Idaho, Washington, Oregon; and 8 weeks annually in Kentucky. Massachusetts requires counties, and New York requires cities to maintain truant schools, or provide for their truants in the truant schools of neighboring localities. Illinois requires cities of over 100,000 inhabitants to maintain truant schools. In Rhode Island towns and cities must provide suitable places for the confinement and instruction of habitual truants. Clothing is furnished in case of poverty to enable children to attend school in Vermont, Indiana and Colorado.

In both the central and the western divisions the education of boys and girls in the same schools is common and exceptions rare in the public schools. In the North and South Atlantic divisions many of the older cities continue to educate the girls in separate schools. In newly added suburban schools, however, coeducation is the rule (as in Boston, for example). In the rural districts of the Atlantic divisions north and south, coeducation has always been the custom. Considering the whole country, it may be said that coeducation, or the education of boys and girls in the same classes, is the general practice in the elementary schools of the United States. The cities that present exceptions to this rule are fewer, apparently, than 6 per cent of the total number. In the majority of these cities the separation of boys and girls has arisen from the position or original arrangement of buildings, and is likely to be discontinued under more favorable conditions. Of the 50 principal cities, four, namely, Philadelphia, Newark, Providence, and Atlanta report separation of the sexes in the high schools only; two cities of this class, San Francisco and Wilmington, reported in 1892, separation in all grades above the primary. In six cities, New York, Brooklyn, Boston, Baltimore, Washington and Louisville, both separate and mixed classes are found in all grades. Five cities of the second class, having a population of 8,000 or more, report separation of the sexes in the high schools, and 10 cities of the same group separate classes in other grades. Of cities whose population is less than 8,000, nine report

EDUCATION

separate classes for boys and girls in some grades. Coeducation is the policy in about two thirds of the total number of private schools reporting to this bureau, and in 65 per cent of the colleges and universities.

In connection with this matter of State compulsory laws against neglect of schools it is well to mention the provisions made in the several States prohibiting appropriations of money to aid denominational schools. There are 40 States with constitutional provisions forbidding all, or at least sectarian, diversion of the money raised for the support of education.

1. *Constitutions which prohibit sectarian appropriations.*—California, Colorado, Florida, Georgia, Idaho, Illinois, Indiana, Louisiana, Michigan, Minnesota, Mississippi, Missouri, Montana, New Hampshire, North Dakota, Oregon, South Dakota, Texas, Washington, Wisconsin, Wyoming—21 States.

2. *Constitutions which do not prohibit sectarian appropriations.*—Alabama, Arkansas, Connecticut, Delaware, Iowa, Kansas, Kentucky, Maine, Maryland, Massachusetts, Nebraska, Nevada, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Rhode Island, South Carolina, Tennessee, Vermont, Virginia, West Virginia—23 States.

3. *Constitutions which prohibit any diversion of the school fund.*—Alabama, Arkansas, California, Connecticut, Florida, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Montana, Nebraska, Nevada, New Jersey, New York, North Carolina, North Dakota, Ohio, Oregon, Pennsylvania, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Washington, West Virginia, Virginia, Wisconsin—36 States.

Manual training is by no means a novelty in American schools. Thomas Jefferson recommended it for the students of the University of Virginia, and Benjamin Franklin included it in his plan for an academy in Philadelphia. An active propaganda was carried on in behalf of manual labor in educational institutions for many years, beginning about 1830, and some of our foremost institutions had their origin under its influence. But what is now known as "manual training" is traced to an exhibit of a Russian institution at the Centennial Exposition in 1876. The value of the system of hand training there suggested was recognized by such men as John D. Runkle and C. M. Woodward, who became advocates of the new idea and introduced it into the institutions under their charge. Strong opposition was met among schoolmen for a time, but manual training has steadily grown in popularity, and with its growth it has constantly improved in matter and method, and consequently in usefulness. In 1898 manual training was an essential feature in the public school course of 149 cities. In 359 institutions other than city schools there is training which partakes more or less of the nature of manual training, and which belongs in a general way to the same movement. These institutions embrace almost every class known to American education, and the manual features vary from the purely educational manual training of the Teachers College in New York city to the specific trade instruction of the apprentice schools. In many cases the legislatures have taken cognizance of the movement. Massachusetts requires every city of 20,000 in-

habitants to maintain manual training courses in both elementary and high schools. Maine authorizes any city or town to provide instruction in industrial or mechanical drawing to pupils over 15 years of age; industrial training is authorized by general laws in Connecticut, Illinois, Indiana (in cities of over 100,000 population), Maryland, New Jersey, New York, Pennsylvania, Utah, Wisconsin and Wyoming. Congressional appropriations are regularly made for manual training in the District of Columbia; Georgia authorizes county manual labor schools, and in Washington manual training must be taught in each school under the control of the State Normal school. See MANUAL TRAINING.

Kindergartens are authorized by general law in Arizona, California, Colorado, Connecticut, Illinois, Indiana, Iowa, Michigan, New York, Ohio, Oregon, Pennsylvania, Vermont and Wisconsin. Cities also establish kindergartens through powers inherent in their charters. In 1897-8 there were public kindergartens in 189 of the 626 cities of 8,000 population and over. In these 189 cities there were 1,365 separate kindergartens supported by public funds. The number of kindergarten teachers employed in this year was 2,532, and under their care were 95,867 children, 46,577 boys and 49,290 girls. Information was obtained concerning 2,998 private kindergartens in 1897-8 and it is probable that at least 500 others were in existence. The 2,998 private kindergartens had 6,405 teachers and 93,737 pupils. It will be seen that the total number of kindergartens, public and private, was 4,363, with 8,937 teachers and 189,604 pupils. The actual number of pupils enrolled in kindergartens in the United States in 1897-8 must have exceeded 200,000, as these reports were not exhaustive.

Education in the United States is regarded as something organic, and as belonging essentially to our political and social structure. We are making the experiment of self-government, and it has seemed a logical conclusion to all nations of all times that the rulers of the people should have the best education attainable. Then, of course, it follows that the entire people of a democracy should be educated, for they are the rulers. This necessity for education has been felt in all parts of the nation, and the whole subject is reasoned out in many a school report published by city or state. By education we add to the child's experience the experience of the human race. His own experience is necessarily one-sided and shallow; that of the race is thousands of years deep, and it is rounded to fulness. Such deep and rounded experience is what we call wisdom. To prevent the child from making costly mistakes we give him the benefit of seeing the lives of others. The successes and failures of one's fellow men instruct each of us far more than our own experiments. The school attempts to give this wisdom in a systematic manner. It uses the essential means for its work in the shape of text-books, in which the experience of the race is digested and stated in a clear and summary manner, in its several departments, so that a child may understand it. He has a teacher to direct his studies and instruct him in the proper methods of getting out of books the wisdom recorded in them. He is taught first in the primary school how to spell out the words and how to write them himself. Above all, he is taught to understand the meaning of the words. All first use of words reaches only a few of their

EDUCATION

many significations; each word has many meanings and uses, but the child gets at only one meaning, and that the simplest and vaguest, when he begins. His school work is to train him into accuracy and precision in the interpretation of language. He learns gradually to fill each word of the printed page with its proper meaning. He learns to criticise the statements he reads, and to test them in his own experience and by comparison with other records of experience. In other words, the child at school is set to work to enlarge his own puny life by the addition of the best results of other lives. This is the clue to the hopes founded on education. The work of the school produces self-respect, because the pupil makes himself the measure of his fellows and grows to be equal to them spiritually by the mastery of their wisdom. Self-respect is the root of the virtues and the active cause of a career of growth in power to know and power to do. Webster explained the effect of the school as exciting "a feeling of responsibility and a sense of character." Each youth educated in the school has been submitted to a training in the habit of self-control and of obedience to social order. He has become to some extent conscious of two selves; the one his immediate animal impulse, and the second his moral sense of conformity to the order necessary for the harmonious action of all. The statistics of crime confirm the anticipations of the public in regard to the good effects of education. The jails of the country show pretty generally the ratio of 8 to 1 as the quotas of delinquents furnished from a given number of illiterates as compared with an equal number of those who can read and write. And it is found on investigation that the criminals who can read and write are mostly from the ranks bordering on illiteracy. They may be described as *barely* able to read and write, but without training in the use of those arts for acquainting themselves with the experience and wisdom of their fellow men. Thus the political problem, which proposes to secure the general welfare by entrusting the management of the government to representatives chosen by all the people, finds its solution in the establishment of schools for the people.

All who become interested in the system of education prevailing in the United States and see the direct bearing it has on the realization of the ideal of self-government, feel an interest in the question of its origin. Immigrants to America in the colonial period laid stress on the establishment of schools. Education is called "the foundation of the commonwealth," in 1583, in a school law of Holland. At that time there was a stringent school law passed. In Sweden education was common before 1650, and every peasant's child was taught to read. Boston, in 1635, voted a school and funds to support a master. Roxbury was quite active in the founding of free schools. Plymouth, Weymouth, Dorchester, Salem, Cambridge, and other towns had schools before 1650. A law of the general court of Massachusetts decreed that in every town the selectmen should prosecute those who refused to "train their children in learning and labor," and to impose a fine of 20 shillings on those who neglected to teach their children "so much learning as may enable them perfectly to read the English tongue." Schools were established in the Connecticut colonies immediately after their settlement. The Rhode Island

colonies had schools by 1650. Meanwhile in New York the Dutch had brought over their zeal for education. The Dutch West India company, in 1621, charged its colonists to maintain a clergyman and a schoolmaster. It seems that in 1625 the colonial estimate included a clergyman at 1,440 florins, and a schoolmaster at 360 florins. In 1633 the first schoolmaster arrived—Adam Roelandson. His name is revered like that of Ezekiel Cheever and Philemon Purmont, schoolmasters of early Boston. New Jersey established schools as early as 1683, and an example of a permanent school fund is found in an appropriation made that year. In 1693 a law compelled citizens to pay their shares for the maintenance of a school. The original charter given William Penn required that the government of his colony should erect and aid public schools. Within 20 years after its settlement, schools were founded in Philadelphia, and others in towns of that colony.

Most of these schools mentioned were more truly secondary than elementary. See EDUCATION, SECONDARY.

The management of the district (elementary) schools began in most cases with the church and gradually came into the hands of the smallest political subdivision, known as "districts." Each township was divided into districts for school purposes, and for minor political purposes such as repair of the public highways. Each district contained an average of four square miles, with a school-house near the centre of population, usually a little distance from some village, and holding a maximum of 40 or 50 pupils. The school committee employed teachers. The schools held a three-months' session in the winter, and sometimes this was made four months. When the villages began to catch the urban spirit and establish graded schools with a full annual session, there came a demand for a higher order of teacher, the professional teacher, in short. This caused a comparison of ideals; the best enlightened in the community began an agitation of the school question, and supervision was demanded. In Massachusetts, where the urban civilization had made most progress, this agitation resulted in the formation of a state board of education of 1837, and the employment of Horace Mann as its secretary (June, 1837). Boston had been connected with Providence, Worcester and Lowell by railroads before 1835, and in 1842 the first great trunk railroad had been completed through Springfield to Albany, opening to Boston a communication with the great West by the Erie canal and the newly completed railroad from Albany to Buffalo. This was the beginning of the great urban epoch in America that has gone on increasing the power of the city to this day. Horace Mann came to the head of education in Massachusetts just at the beginning of the epoch of railroads and the growth of cities. He attacked with unsparing severity the evils of the schools as they had been. The school district system, introduced into Connecticut in 1701, into Rhode Island about 1750, and into Massachusetts in 1789, was pronounced by him to be the most disastrous feature in the whole history of educational legislation in Massachusetts. Horace Mann extended his criticisms and suggestions to the examination of teachers and their instruction in teachers' institutes; to the improvement of school buildings; the raising of school funds by taxation; the

EDUCATION

creating of a correct public opinion on school questions; the care for vicious youth in appropriate schools. He discarded the hide-bound text-book method of teaching and substituted the oral discussion of the topic in place of the memorizing of the words of the book. He encouraged school libraries and school apparatus. Horace Mann's influence founded the first normal school in the United States at Lexington (afterward moved to Framingham), and a second one founded at Bridgewater in the fall of the same year (1839). Inspired by the example in Massachusetts, Connecticut was aroused by Henry Barnard, who carried through the legislature the act organizing a state board of commissioners, and became himself the first secretary of it (1839). In 1849, Connecticut established a normal school. In 1843, Mr. Barnard went to Rhode Island and assisted in drawing up the state school law under which he became the first commissioner, and labored there six years.

These were the chief fermenting influences in education that worked a wide change in the management of schools in the middle and western States within the past 50 years. Superintendents of city school systems began in 1837 with Buffalo. Providence followed in 1839; New Orleans in 1841; Cleveland in 1844; Baltimore in 1849; Cincinnati in 1850; Boston in 1851; New York, San Francisco and Jersey City in 1852; Newark and Brooklyn in 1853; Chicago and St. Louis in 1854; and finally Philadelphia in 1883. State superintendents began with New York, 1813; New York was followed by 16 of the States before 1850. From 1851 to the Civil War, eight States established the office of State superintendent; since then, 19 other States, including 10 in the South, that had no State systems of education previously. Normal schools in the United States increased from one, beginning in 1839 in Massachusetts, to 138 public and 46 private normal schools in 1889, with an attendance of upwards of 28,000 students preparing for the work of teaching. This would give a total of some 12,000 a year of new teachers to meet the demand. It may be assumed, therefore, that less than one sixth of the supply of new teachers comes from the training schools specially designed to educate teachers. The history of education since the time of Horace Mann is very largely an account of the successive modifications introduced into elementary schools through the direct or indirect influence of the normal school.

W. T. HARRIS,

U. S. Commissioner of Education.

Education, Kindergarten. See KINDERGARTEN EDUCATION.

Education, Medical. See MEDICAL EDUCATION.

Education, Negro. See NEGRO, EDUCATION OF.

Education, Professional, in America. At the time of the Declaration of Independence there were only two professional schools in the United States, the Medical College of Philadelphia (1765), now the medical department of the University of Pennsylvania, and the medical department of King's College (1768), now Columbia University.

The following statistics for the year 1901, as prepared by the commissioner of education,

show a remarkable growth in this particular phase of education in the United States:

CLASS OF SCHOOLS	Schools	Instr't's	Students	Graduates
Theological	150	988	7,567	1,585
Law	100	1,106	13,642	3,366
Medical	154	4,752	26,757	5,472
Dental	57	1,184	8,308	2,311
Pharmaceutical . .	58	522	4,429	1,373
Veterinary	12	189	461	109
Nurse Training . .	448	11,599	3,710
Totals	979	8,741	72,763	17,926

In 1901, the total amount of property controlled by these schools was estimated at \$130,093,681. Of this total, however, \$96,188,818 is credited to hospitals where there are schools for nurse training. This leaves \$33,904,863 in property invested in the 531 professional schools proper. The income of these institutions amounts to \$3,492,141, and the number of volumes in the school libraries is nearly 3,000,000.

Among the 150 theological schools are 28 Roman Catholic institutions, 29 Presbyterian, 12 Baptist, 22 Lutheran, 10 Congregational, 13 Protestant Episcopal, and 18 of other denominations.

There is no national authority in the United States that can prescribe standards for degrees or for license to practise the professions. Each State makes its own professional laws. As a result there are almost as many standards as there are political divisions. The desirability of uniform standards throughout the country for admission to professional practice is recognized generally, but varying conditions as to density of population, educational advantages, and general development make it impracticable to hope for the attainment of this end for some time to come. In 1850 the public had little protection from incompetency in professional practice. The bar is said to have been at its lowest ebb. Medical laws were crude and largely inoperative. In several States only were there any acts designed to control the practice of pharmacy and dentistry. There was no law whatever restricting the practice of veterinary medicine. There has been extraordinary progress, especially in the last decade, in restrictive professional legislation, and in the admission and graduation requirements of professional schools throughout the United States. In New York State a preliminary general education equivalent to graduation from a four years' high school course after a completed eight years' elementary course is prescribed by statute as the minimum standard for license to practise medicine. This standard approximates that required in continental Europe. New Hampshire has similar requirements, but they are not as rigidly enforced. The statutes of Delaware, Maryland, New Jersey, and Pennsylvania prescribe a "common school education." Louisiana demands "a fair primary education." The rules in Vermont prescribe a high school course; in Illinois and Iowa less than one year of high school work; in Virginia, "evidence of a preliminary education." In remaining political divisions laws and rules are either silent in this respect or so indefinite as to be of little value.

In New York and Illinois a preliminary general education equivalent to a three years' high school course is required for admission to the bar. Connecticut demands a high school

EDUCATION

education or an indefinite preliminary examination. The minimum requirement in Michigan (in case of examination) is less than two years of high school work, in Colorado it is one year of high school work, in Minnesota (in case of examination) it is less than one year, in Ohio it is a common school education. If anything is demanded in other political divisions the requirement is not sufficiently established (excepting a few local cases) to find a place either in statutes or court rules.

The New York law exacts a full high school course as one of the requirements for license to practise dentistry. New Jersey demands by statute "a preliminary education equal to that furnished by the common schools," Pennsylvania "a competent common school education," Virginia a "fair academic education." In other political divisions there is no such requirement. Louisiana, Michigan, South Dakota, Wisconsin, and, in case of examination, California and Texas are the only political divisions which mention in their rules preliminary general education as a requirement for license to practise pharmacy. An elementary education only is prescribed. The completion of a full high school course or its equivalent is one of the statutory requirements for license to practise veterinary medicine in New York. Pennsylvania demands "a competent common school education." There is no such requirement in any other State.

In New York, high standards in preliminary general education are demanded both for degrees and for licenses, and in each case the question of attainments is determined by a central authority, the University of the State of New York. As a rule in other States the professional schools conduct their own entrance examinations, and the tests are often mere matters of form, even though the standards may appear satisfactory on paper.

Entrance Requirements.—In 4 theological schools there are no entrance requirements; in 24 schools they are indefinite; 19 demand a grammar school education; 1, 6, and 19 require respectively one, two, and three years of high school work; 18, 3, and 71 demand respectively one, three, and four years of college work.

In 16 law schools there are apparently no entrance requirements whatever; in 8 schools they are so indefinite as to be practically worthless; 26 schools demand a grammar school education; 8, 11, 12, and 3 require respectively one, two, three, and four years of high school work. Harvard demands an education equivalent to that required for admission to the senior class. The Columbia Law School is maintained as a graduate department after 1903.

In 2 medical schools the requirements are indefinite; 29 demand a grammar school education; 97, 12, 3, and 12 require respectively one, two, three, and four years of high school work. Johns Hopkins and Harvard require a college course.

In 3 dental schools the requirements are indefinite; 18 demand a grammar school education; 18, 11, and 6 require respectively one, two, and three years of high school work.

In 6 schools of pharmacy there are no entrance requirements; in 4 schools they are indefinite; 24 demand a grammar school education; 11, 6, and 1 require respectively one, two, and three years of high school work.

In 1 veterinary medical school the require-

ments are indefinite; 9 demand a grammar school education; 1, 5, and 1 require respectively one, two, and three years of high school work.

Courses in theology, law, and medicine are naturally graduate courses and will eventually be maintained as such by leading universities. It is believed, however, that it would not be advisable or even desirable for the State to make graduation from college the minimum requirement in general education for degrees even in these faculties. High school graduation is sufficient for the minimum State requirement.

University Supervision.—As long as the public had practically no protection from incompetency in professional practice independent proprietary schools flourished. With proper restrictive legislation such institutions will either die or fall under university supervision.

Many professional schools not under university supervision show a self-sacrificing zeal for high standards and an absence of the commercial spirit that might well be emulated by all institutions connected with colleges or universities. Nevertheless independent institutions are realizing more than ever before the disadvantages of working without university privileges and tend more and more toward university connections or university relations.

Scholarships.—Theological seminaries, when not endowed, are supported by funds from the denominations they represent. Tuition is generally free, and in many cases board and lodging are furnished. Additional help is given usually when needed, and generous scholarships are the rule. In other professional schools scholarships are comparatively rare. The latest United States education report gives 40 law school scholarships and 295 medical school scholarships. The largest, offered by College of Physicians and Surgeons, New York, pays \$700 a year and is bestowed to promote the discovery of new facts in medical science.

An examination of 82 law school catalogues shows that 48 scholarships are offered definitely. Tuition is free at the law department of Howard University, the law departments of the universities of Kansas, Texas, and West Virginia. The Harvard law school and the Boston University law school offer a "limited number of free scholarships." Law students may compete for the 150 State scholarships and the 18 university scholarships offered annually at Cornell and for the 50 city scholarships offered by the University of Pennsylvania. The law department of Centre College offers free tuition to sons of ministers and to all young men of limited means and good character. Three schools give fellowships annually as follows: New York Law School, 1 at \$500 a year, good for from one to three years; law department University of Pennsylvania, 1 at \$300, good for one year; Pittsburg Law School, 1 at \$250, good for one year. Thirty-two schools offer cash prizes amounting to \$3,010 and law and reference books as other prizes.

One hundred and fifty-one medical school catalogues report definitely only 152 scholarships and 11 fellowships. These are offered by 31 schools. Five other schools refer indefinitely to scholarships. At Cornell and the University of Pennsylvania medical students may compete for State and university, or city scholarships on an equal footing with those who would enter other departments. Tuition is free at the Army

EDUCATION

Medical School, the medical department of the University of Texas, and the medical preparatory school of the University of Kansas. Nineteen schools give cash prizes amounting to \$5,685; 57 offer hospital appointments as prizes; 47 give gold medals, surgical instruments, and other prizes.

Fifty-six dental school catalogues show that 7 schools offer 58 scholarships. The dental department of the University of Maryland deducts one half from tuition fees of one student from each State on recommendation of his State dental society. The Baltimore College of Dental Surgery had similar beneficiary scholarships till 1898 when they were abolished. Eighteen schools offer prizes but their value is not great.

Fifty-two catalogues of schools of pharmacy show that 5 schools offer 12 scholarships and 2 fellowships. Tuition is free at the schools of pharmacy connected with the Alabama Polytechnic Institute, Washington Agricultural College, Purdue University, and the universities of Kansas, Ohio, Oklahoma, Texas, Washington, and Wisconsin. Fifteen schools offer prizes, usually medals or pharmaceutical instruments. Five of these 15 schools give cash prizes amounting to \$620. The committee on revision of the 'United States Pharmacopoeia' has instituted fellowships in the University of Michigan and the University of Wisconsin for the discovery of new facts in pharmacy.

Sixteen veterinary school catalogues show that 19 scholarships are offered at 5 schools, that 1 school gives a fellowship and that 6 schools offer prizes. Tuition is free at the veterinary departments of Cornell and Ohio universities, and of Washington Agricultural College. Cornell opens to competition by veterinary students, 18 scholarships and to veterinary graduates a fellowship of an annual value of \$500. Veterinary matriculates are eligible for 50 city scholarships offered by the University of Pennsylvania. The veterinary department of Ohio State University offers a scholarship in each county in which the agricultural scholarship is not taken.

Fees.—Tuition is free in 132 theological schools. Only 8 have matriculation fees, 33 a course fee, and 34 other fees. The average matriculation fee is \$5.38, the average course fee \$91.61, the average of other fees \$22.06.

Tuition is free in 4 law schools; 23 have matriculation fees (average \$14), 83 have course fees (average \$69.80), 59 have other fees (average \$10.86).

Tuition is free in 3 medical schools; 119 have matriculation fees (average \$10.68), 153 have course fees (average \$82.39), 129 have other fees (average \$49.47).

Tuition is not free in any dental school; 40 have matriculation fees (average \$8.62), 56 have course fees (average \$94.32), 5 have other fees (average \$33.48).

Tuition is free in 9 schools of pharmacy; 28 have matriculation fees (average \$8.07); 43 have course fees (average \$58.90), 50 have other fees (average \$37.90).

Tuition is free in 3 veterinary medical schools; 7 have matriculation fees (average \$7.85), 14 have course fees (average \$81.28), 12 have other fees (average \$43.50).

Libraries.—In 1901 the United States commissioner of education reported 1,531,038 vol-

umes in libraries of theological schools, 338,167 in libraries of law schools, 187,207 in libraries of medical schools, 6,860 in libraries of dental schools, 30,216 in schools of pharmacy libraries.

Endowments.—The report (1901) of the commissioner of education gives the following figures:

CLASS OF SCHOOLS	Endowment Funds	Benefactions received during the year
Theological	\$21,165,174	\$946,473
Law	1,151,920	103,000
Medical	2,048,182	209,192
Dental		
Pharmaceutical	23,726	
Veterinary		4,500
Nurse Training (Hospitals) ..	18,967,377	2,124,582

Value of Grounds and Buildings.—In 1901, the following figures were given, showing the value of grounds and buildings of professional schools:

Theological	\$15,217,164
Law	1,875,000
Medical	14,472,635
Dental	1,213,122
Pharmaceutical	836,442
Veterinary	270,500
Nurse Training (Hospitals)	96,188,818

The following report the greatest values in grounds and buildings:

Theology	
General Theological Seminary, Protestant Episcopal	\$1,353,000
St. Joseph's Seminary, Roman Catholic	1,100,000
Western Theological Seminary, Presbyterian ..	780,955
Law	
University of Cincinnati, law department	350,000
Boston University Law School	225,000
Medicine	
Columbia University, medical department	2,000,000
Jefferson Medical College	600,000
Hahnemann Medical College, Philadelphia	523,763
Cooper Medical College	460,000
Dentistry	
Baltimore Medical College, dental department ..	200,000
Philadelphia Dental College	170,000
New York College of Dentistry	120,000
Pharmacy	
New York College of Pharmacy	204,067
Philadelphia College of Pharmacy	150,000

When grounds and buildings are used for several departments, as for example the Columbia Law School which is in the library building, values are not always reported.

Receipts and Expenditures.—The latest reports available for 1898 give only a partial report of receipts and expenditures as follows:

TOTAL.				
CLASS OF SCHOOLS.	No. of Schools	Receipts	Schools	Expenditures
Theology	76	\$1,561,516	83	\$1,420,921
Law	31	565,295	33	540,887
Medicine	111	2,185,216	111	2,022,503
Dentistry	23	459,996	22	421,680
Pharmacy	13	167,098	13	173,994
Veterinary Med.	8	86,598	8	89,604
	262	\$5,025,719	270	\$4,669,598

AVERAGE.				
CLASS OF SCHOOLS.		Receipts		Expenditures
Theology		\$20,546	26	\$17,119 53
Law		18,235	32	16,390 52
Medicine		19,686	63	18,220 74
Dentistry		19,999	82	19,167 68
Pharmacy		12,853	69	13,384 75
Veterinary Medicine		10,824	75	11,200 50

EDUCATION

Women as Professional Students.—The 1901 United States education report shows that women now appear as students in professional schools of each class except those in veterinary medicine. In nursing they are of course in a large majority, 10,292 as compared with 1,307 men. In the other professions they are reported as follows: Theology, 181, law 170, medicine 1,219, dentistry 166, pharmacy 206. The proportion of women in regular medical schools is much smaller than in homœopathic, eclectic, and physiomedical schools, showing that women prefer the medical sects.

See DENTISTRY; EDUCATION; LAW; MEDICINE; NURSES, *Trained*; PHARMACY; THEOLOGY; VETERINARY; WOMEN, EDUCATION OF.

Power to Confer Degrees.—Low standards in many professional schools are due to a failure to subject the degree-conferring power to strict State supervision. In New York and Pennsylvania the laws now prevent an abuse of the power to confer degrees. In Massachusetts and Vermont bodies formed under the general corporation acts are prohibited from conferring degrees. In Ohio and Nebraska the statutes require only the nominal endowment of \$5,000 for a degree-conferring institution. In other States and Territories as a rule any body of men may form an educational corporation with power to confer degrees "without any guaranty whatever that the privilege will not be abused." This matter has been under discussion recently in various educational bodies and there is a strong sentiment in favor of a strict supervision by the State of the degree-conferring power.

Bibliography.—It is impossible to give more than a brief outline of professional education in the United States. For detailed information touching laws, regulations, location of schools, and courses of study the reader is referred to 'Professional Education in the United States,' published by the University of the State of New York. Of the many authorities the following are most helpful: United States education reports; Eliot, 'Educational Reform'; United States census reports; Briggs, 'Theological Education, and Its Needs'; Dyer, 'Theological Education in America'; Jessup, 'Legal Education in New York'; Wellman, 'Admission to the Bar'; Hammond, 'American Law Schools, Past and Future'; reports of the American Bar Association; Toner, 'Annals of Medical Progress in the United States'; Davis, 'Medical Education and Medical Institutions in the United States'; Journal American Medical Association; Shepard, 'Inaugural Address at the World's Columbian Dental Congress'; 'Proceedings of the American Pharmaceutical Association.'

JAMES RUSSELL PARSONS,
University of the State of New York.

Education, Roman Catholic, in America. The educational work conducted under the auspices of the Roman Catholic church in the United States embraces all grades of institutions, from the kindergarten to the university. The official figures for the year 1903 show 4,001 parishes with parochial schools, 646 academies and high schools for girls, 179 colleges for boys, and 7 universities. At least four of these universities, by reason of their collegiate and professional courses, deserve to rank as universities, in the proper acceptance of the term. At the head of the Catholic school system is the Catho-

lic University of America, Washington, D. C., established canonically by Pope Leo XIII., 10 April 1887, and incorporated the same year under the laws of the District of Columbia, with Rt. Rev. John J. Keane, S. T. D., as rector.

About one hundred religious teaching orders of men and women and select bodies of the diocesan clergy conduct this work, with a variety of methods and courses of study, but with a unity of purpose to impart a thorough Christian education to the Catholic youth of the country. In the secular studies, the curricula of schools, academies, colleges, and universities do not differ materially from those that obtain in other American schools. In many instances they are recognized by city or state departments of public instruction, and prepare the students for entrance into the higher public institutions of learning. Throughout all schools and grades the study and practice of the Catholic religion are made important; indeed, it is this solicitude of the church for the influence of Christian faith and morals upon the conscience and character of youth that has called forth and maintains, at immense cost and sacrifice, these thousands of Catholic schools. The Catholic Church considers the Christian religion essentially requisite for shaping the character and regulating the life of her youth, and therefore insists upon its action in her schools, to develop a sense of Christian duty, of obligation, of right and wrong, in conscience and before God. The aim of the church and its attitude toward State schools, wherein the teaching of religion is prohibited, are clearly set forth in the pastoral letter of the American bishops of the Third Plenary Council:

Reason and experience are forcing all Christian denominations to recognize that the only practical way to secure a Christian people, is to give the youth a Christian education. The avowed enemies of Christianity in some European countries are banishing religion from the schools, in order to eliminate it gradually from among the people. In this they are logical, and we may well profit by the lesson. Hence the cry for Christian education is going up from all religious bodies throughout the land. And this is no narrowness nor "sectarianism" on their part; it is an honest and logical endeavor to preserve Christian truth and morality among the people by fostering religion in the young. Nor is it any antagonism to the State; on the contrary, it is an honest endeavor to give to the State better citizens, by making them better Christians. The friends of Christian education do not condemn the State for not imparting religious instruction in the public schools as they are now organized; because they well know it does not lie within the province of the State to teach religion. They simply follow their conscience by sending their children to denominational schools, where religion can have its rightful place and influence.

Catholic Secondary Schools.—There is no single, organized system of Catholic secondary schools in the United States. Between the parish school system, now fairly well organized in most dioceses with school superintendents, courses of study, grading of classes, etc., and the university at Washington, there is no uniform plan of intermediate studies. Each secondary school and college is a law unto itself respecting entrance requirements, length and character of courses, and standards for graduation, except in so far as these are regulated by the chartering power under which degrees or honors are conferred. Nor are there any free, endowed Catholic secondary schools besides the Boys' Catholic High School, Philadelphia, founded by the late Mr. Cahill, and the Creighton University, Omaha, Neb., founded by John A. Creigh-

EDUCATION

ton. The secondary schools that do exist are maintained by the teaching orders, mainly through the tuition fees of the students. Living a community life and working without salary, these teachers have been enabled to accomplish much with inadequate resources, and their contribution to the church's educational work in the United States is beyond reckoning. Were it not for their self-sacrifice and devotion to the cause of education, the American Catholic youth would have scarcely any means of prosecuting the higher studies under Catholic auspices. Within the past 10 years efforts have been made with success in several dioceses to secure the foundation of free scholarships for ambitious and deserving graduates of the parish schools.

Academies and High Schools.—Under this heading are included the convent schools for girls, manual and industrial training schools for boys, commercial and high schools for both sexes. The elementary course of eight years is supplemented by a course varying from one to four years, in the higher studies of English, languages, science, mathematics, history, commercial studies, art and music, and Christian ethics. Last year there were 646 academies for girls with an attendance of about 25,000.

The manual and industrial training schools are not so numerous, but with the growing demand for artistic work in the trades, each year marks the opening of new trade schools. The Catholic High School, Philadelphia, and the Papal College Josephinum, Columbus, Ohio, are noted for their excellent work. Commercial schools for boys are found in every large city as preparatory schools for those intending a business career. Many parish schools give post-graduate courses in commercial law, bookkeeping and typewriting, and might properly be classed with secondary schools. For some time there has been a tendency to advance the larger parish schools beyond the studies of the grammar grades. One or more advanced classes are devoted to secondary work. At present there are about 50 of these in the larger cities, with an attendance of 450 boys and 750 girls. These figures are not large but they are significant of a growing demand for the advantages of Catholic secondary education.

Less than half of these Catholic academies have reported statistics to the United States Commissioner of Education. Of the 1835 private secondary schools reporting to the Commissioner, religious denominations control 923. Of the latter, the Catholic Church maintains 369, with 1,946 instructors, and 16,786 students, distributed as follows:

	Schools	Instructors	Students
North Atlantic States....	99	556	5,385
South Atlantic States....	35	163	1,227
South Central States....	53	268	2,485
North Central States.....	116	675	5,426
Western States	66	284	2,263

History.—One of the first high schools for boys in the United States was the classical school founded in 1682 by the Jesuits, in that part of New York city known as "Bowling Green," near the Battery. It was patronized by Gov. Thomas Dongan and by the best Protestant families of the time. Later it had to be closed owing to attacks of bigotry, rampant in that age, but in 1808, Father Antony Kohlmann, administrator of the diocese, bought ground for a new school, in front of the old cathedral. It was opened with

one priest, and four scholastics, and had 35 pupils. A few years after it moved to the site of the present Cathedral, and developed into the diocesan seminary. Among the earliest American academies for girls was the pioneer Ursuline Academy in Canada, founded by Madame de la Peltrie, in 1652. The original building forms the centre of that group which to-day constitutes the Ursuline Convent, Quebec. The first band of Ursulines in the United States reached New Orleans in 1727, and established on August 7, that year, what is probably the first high school for girls in this country. In 1808 Ursulines from Ireland opened an academy in New York city, but failing to receive vocations to the Order, they returned home. In 1820, the historic Ursuline school at Charlestown, Mass., was opened, and at once attracted attention for the excellence of its work. It is said that four fifths of its pupils were from the most distinguished Protestant families of New England. The Visitation Nuns began their educational work in the United States at Georgetown, D. C., in 1799. The saintly Mother Eliza Anne Seton, a convert to the Catholic faith, established in 1809 at Emmetsburg, Md., the Sisters of Charity of Saint Joseph. In 1812, at Nazareth, Ky., a few pious ladies founded the Sisters of Charity of Nazareth, with Mother Catharine Spalding, the first superioress, and in 1818 the Ladies of the Sacred Heart came to the United States, when Madame Duchesne opened a convent at Saint Charles, Mo. Since then other Orders from the old world came here to organize and conduct schools and at least 20 more are original American foundations.

Catholic Colleges.—These may be classified as classical, commercial, and a combination of both. They arose to meet the demand for higher education by those destined for the priesthood, the learned professions, and business careers. The tendency to-day is to eliminate the commercial department from the colleges, and thus make them strictly classical and scientific. The Christian Brothers, who had attained distinction in the teaching of the classics, have returned to their primitive rule which forbade this teaching, and are now making a specialty in their colleges of the modern languages, pedagogy and applied science. Excepting Creighton College, Omaha, Neb., there is no free, endowed Catholic college in the United States. Tuition fees have been the main source of revenue; benefactions and endowments have been a rarity; not one Catholic institution appears on last year's list of notable benefactions to American colleges. Lack of funds has hampered many of the colleges in extending the field of their labors and in undertaking many modern methods and improvements. No uniform, definite standard obtains for entrance. In the East an increasing number conform to the requirements of the Regents of the University of New York, or to the regulations of "The Association of Colleges and Preparatory Schools in the Middle States and Maryland." Under the guidance of Rt. Rev. Mgr. Thomas J. Conaty, D. D., rector of the Catholic University, the representatives of 53 Catholic colleges assembled in Chicago in 1899, and organized "The Association of Catholic Colleges of the United States." The purposes of the association are to study the questions connected with college education, to advance the unification of sys-

EDUCATION

terms of Catholic education, and to strive toward a larger development of college work. The Association meets at an annual conference, the report of which is published at the Catholic University. Its organization was perhaps the most important step taken in Catholic higher education since the establishment of the Catholic University.

The colleges are conducted chiefly by the religious teaching orders of men, as follows: Augustinians, 2; Benedictines, 18; Capuchins, 2; Carmelites, 1; Order of Charity, 1; Christian Brothers, 6; Franciscans, 5; Franciscan Brothers, 1; Holy Cross, 5; Holy Ghost, 1; Jesuits, 24; Marists, 5; Society of Mary, 4; Precious Blood, 1; Brothers of the Sacred Heart, 4; Saint Viateur, 1; Vincentians, 2; Zaverian Brothers, 3. Not all of these are reported by the United States Commissioner of Education. In the 60 colleges for which statistics are given, there were (1902-3) 1,375 instructors and an attendance of 14,158 students.

Colleges for Women.—The Catholic Church has ever been solicitous to foster the higher education of women, but on lines that will conserve the graces and promote the ideals of true Christian womanhood. The Ursulines and the Ladies of the Sacred Heart conduct several collegiate schools. At Govanstown, Md., the School Sisters of Notre Dame maintain a promising college. Saint Mary's, Notre Dame, Ind., Sisters of the Holy Cross, was founded in 1855 to provide for the highest education as rapidly as means would allow. This is probably the first legally authorized Catholic college for women in the United States, its charter from the Indiana legislature dating back to the year of foundation. The new Collegiate Hall was opened last year. The College of Saint Elizabeth, formerly known as the Academy, Convent Station, N. J., was founded in 1859 and is in charge of the Sisters of Charity. It is chartered under the laws of New Jersey to confer degrees, and is registered by the N. Y. Board of Regents. Its physical and chemical laboratories are splendidly equipped with all modern appliances for advanced work in all the college departments. Saint Mary's-of-the-Woods, Saint Mary's, Ind., was established by the Sisters of Providence, in 1840, and for some years has been empowered to confer academic honors and collegiate degrees. Trinity College, Washington, D. C., in the immediate vicinity of the Catholic University, was organized in 1901 by the Sisters of Notre Dame of Namur, and is strictly a post-graduate college. It is a woman's college of the same grade as Vassar, thus giving Catholic women an opportunity for receiving the highest collegiate instruction.

Universities.—Among the Catholic institutions of highest education are the universities of Georgetown, Notre Dame, Creighton, and the Catholic University of America. Saint John's College, Fordham, N. Y., founded in 1841, announces that it will branch out as a university this year, when a medical college will be opened, affiliated in a clinical way with a new hospital in course of erection near by. The oldest Catholic university in the United States is Georgetown, District of Columbia, founded in 1789. It contains a graduate school, collegiate, law, medical and preparatory departments, and an astronomical observatory. The Jesuit Fathers conduct it.

Notre Dame University, Saint Joseph County, Ind., was established 1842 by the Very Rev. Edward Sorin, C. S. C. It has thirteen full collegiate courses, besides excellent courses in art and music. The Creighton University, Omaha, Neb., founded by John A. Creighton and endowed as a free college, was opened in 1879, in charge of the Jesuits. It includes Creighton College, a free, classical day college, and the Creighton Medical College (1892), with a clinic in The Creighton Memorial Saint Joseph's Hospital. The Catholic University of America, Washington, D. C., was established by the American bishops through the munificence of Miss Mary Gwendolin Caldwell. It was solemnly opened 13 Nov. 1889, as the highest seat of learning of the Catholic Church in the United States. By the terms of its Constitutions "the courses of study shall be such in quality and grade as befit a real university." Under the Faculties of theology, philosophy, and law, and the Board of Instruction of Technology are maintained twenty-five departments of university study. The University Colleges, managed by officers under rules laid down by the Board of Trustees, of which His Eminence James Cardinal Gibbons is president, are Divinity College, or Caldwell Hall, and Keane College, named in honor of the University's first Rector, Most Rev. Archbishop John J. Keane, Dubuque, Iowa. Affiliated with the University and grouped about it are Saint Thomas' College (Paulists), Marist College (Society of Mary), Holy Cross College (Fathers of the Holy Cross), College of the Holy Land (Franciscans), Saint Austin's College (Sulpicians), and the Apostolic Mission House (Catholic Missionary Union). Saint Paul's Seminary, Saint Paul, Minn., is also an affiliated college. McMahon Hall, named in honor of the late Mgr. James McMahon, who founded it, contains the chief lecture halls and laboratories. Among the University publications are the 'Catholic University Bulletin,' published quarterly; 'Pittonia,' a series of papers relating to botany; and the 'Year Book,' published annually in April.

Normal Schools.—The religious orders of men and women devoted to educational work prepare their novices at their respective mother-houses, which are normal schools, with more or less full courses in pedagogy. Many of these are distinct buildings, equipped with the best appliances used in modern training schools for teachers. The normal institutes of the Christian Brothers at Amawalk and Ammendale, of the Notre Dame Sisters at Waltham, Mass., and San Jose, Cal., and of the Marist Brothers at Dayton, Ohio, are model institutions. In the United States Commissioner's report are the statistics of twelve others, in which the curriculum of normal studies is followed by 215 students. In 1873 Mother Angela, Sisters of the Holy Cross, Notre Dame, Ind., established Saint Catharine's Normal School, at Baltimore, Md. This was the first Catholic Normal school for women in the United States. Its course of study has always been in accord with the best pedagogic methods. Of late years the Jesuits and the Christian Brothers have conducted special pedagogical departments in most of their colleges. In October 1903, the Catholic University opened in New York city an Institute of Pedagogy, where its professors give graduate courses in psychology, logic and ethics, principles,

EDUCATION

methods, and history of education, American history, and library work.

Catholic Reading Circles.—The first Catholic reading circle was begun by Warren E. Mosher, in Youngstown, Ohio, in 1889. He also founded and edited the 'Catholic Reading Circle Review,' the monthly organ of the Catholic Educational Union. Under the name of the 'Champlain Educator,' the Review is now the official organ of the Catholic Summer School of America. The same year the Paulist Fathers (N. Y.) established the Columbian Reading Union, with a department in the 'Catholic World Magazine.' Under the Catholic Educational Union, 200 reading circles are organized, with a membership of 6,000; in the Columbian Reading Union are 150 reading circles, with a membership of more than 5,000. The most far-reaching and progressive outgrowth of the movement has been the University extension work through the Catholic Summer and Winter Schools, organized on the well-known Chautauqua plan. The parent Catholic Summer school was established at New London, Conn., in 1892. A year later permanent grounds consisting of 500 acres were secured at Cliff Haven, on the west bank of Lake Champlain. In 1903, 6,000 people were in attendance. The investments of the Catholic Summer School of America represent over \$400,000. The lecture courses embrace literature, art, science, pedagogy, history, philosophy, music, physical culture, and ethics. The New York State Department of Public Instruction has established the Summer School as a summer institute for teachers, and the course in pedagogy qualifies for promotion before the Board of Education, New York city. In 1895 a similar organization was effected in the middle West, at Madison, Wis., where the successful Columbian Catholic Summer School holds its sessions. The Catholics of the South in 1896 opened a Catholic Winter School in New Orleans, where its annual session opens each year after the Mardi Gras celebration. San Francisco also has its Catholic Winter School, and at Emmetsburg, Md., have been held five annual sessions of the Maryland Catholic Summer School.

Diocesan Inspector of Schools, Brooklyn, N. Y.

Education, Roman Catholic in Canada.
See CANADA — CATHOLIC EDUCATION.

Education, Scientific and Technical. The development of the schools of science and technology in the United States is, practically, an affair of the last half of the 19th century. In a large measure the same is true of similar institutions in Europe, for although there are isolated examples of earlier foundations it is only during the past 50 years that in number and importance they have come to rank with older systems of intellectual and professional training. Their comparatively recent origin is readily accounted for when it is remembered that they are nearly all schools in which science is taught with a

view to its practical application and that the admission to the college curriculum of any part of what is now generally included under the term "science" was a rare novelty in the early part of the century. The modern scientific school or engineering college is largely indebted for its being to Archimedes, Galileo, Bacon, Kepler, Newton and a host of others who by creating exact science made applied science possible. The idea of a school of science or of a college in which the applications of scientific discovery might be taught was of slow growth at the beginning, and naturally so, for their successful development demanded the evolution of methods of instruction entirely new and often in violation of accepted tradition. A class of professional schools had existed, indeed, almost as long as education itself, namely, schools for training candidates for the so-called "learned" professions, law, medicine and theology, but it will not be claimed that they had much in common, either as to method or material, with the modern school of science.

The earliest technical schools, those of 100 years ago or more, almost without exception, grew out of the industrial demands of the locality in which they were founded. One of the best examples is the famous School of Mines at Freiburg which has enjoyed a long and illustrious career and many of the earlier European schools belong to the same class. To these and the more modern schools of science and technology the United States is greatly indebted, especially on account of the generous welcome that has always been extended to American students and for the inspiration with which many of them have returned to take their part in the wonderful educational evolution which the last half century has witnessed. But in all cases European methods have been adapted rather than adopted. Political, social and material conditions have largely influenced educational foundations, and while the nearly 100 schools of science and engineering scattered over the United States have many points of resemblance, there is much individuality, particularly among the strongest and best, and it is believed that their several types represent important advances in the direction of scientific and technical education which will not be without interest to educators in other parts of the world.

A not very exact classification based on organization easily divides scientific and technical schools into three groups. In the first group are those schools and colleges practically devoted to science and technology exclusively, which have independent foundations and which are not under state or government control. These have almost invariably originated in private endowment, often of one man, and rely for their support upon the income from their endowment and from tuition fees. The second group embraces those schools which are closely affiliated with other colleges or schools forming universities, sometimes without a distinctly separate faculty or special organization, whose work has been largely individualized, sometimes having a distinguishing name, and not under state or government control. Some members of this group are wholly or partly supported by separate endowments and fix and collect their own tuition fees, while others depend upon sharing the common resources of the larger whole of which they are a part. In the third group are included that

EDUCATION

very large and important class of schools supported largely, if not entirely, by state and government appropriation. The organization of some of these resembles in an important particular that of the first group in the fact that they enjoy a separate existence as schools of science or technology, being independent of any college or university affiliation. The majority, however, are not thus independent, and must be regarded as departments of a college, or schools or colleges of a university. A few of them originated in private endowments and do not rely entirely on the state or national government for support, but yet are so largely dependent on that source of revenue that they fairly belong to the group. Something of the origin, history and development of a few of the principal representatives of these three groups will be given, to be followed by some general statements relating to requirements for admission, courses of study, degrees and other matters of interest or importance.

The first endowment and organization of a school of science in the United States was that of the Rensselaer Polytechnic Institute in 1824. Others followed later, for the history of which the reader is referred to the proper title. The requirements for admission are by no means uniform, nor are they extremely varied. Perhaps the typical average requirements for admission to schools of science or engineering colleges would include—besides the “common English branches”—algebra, plane geometry, English literature, history of the United States and either the French or German language. About two to three years’ study of the latter would be required, and to this list will often be added solid geometry, plane trigonometry, the elements of physics or chemistry, and sometimes a year or two of Latin. There seems to be a growing tendency toward the introduction of a large number of electives among the subjects required for admission.

The leading institutions or departments of institutions in which special attention is given to pure and applied science do not differ materially in their organization, courses of study or degrees conferred. Practically all courses are four years in length, in nearly all the first two years are largely preparatory to the special or professional work of the last two, embracing modern languages, mathematics and a few other subjects, most of which are common to all courses offered. The differentiation begins generally at the opening of the junior or third year, although in some cases it must commence earlier. In the matter of degrees the great majority of schools confer only the degree of bachelor of science at the end of the four years’ course, but there are a few that offer the so-called professional degrees such as C. E., M. E., etc., for the mastery of a four years’ course. The requirements for graduate degrees are tolerably uniform, being usually a year of resident study with the preparation of a thesis for the master’s degree, and in addition to this usually three years’ successful professional work with an acceptable thesis for a professional degree. The history of the growth of technical schools shows the enormous educational advance which has taken place during the past 15 or 20 years throughout the whole country, and especially in what is known as the “Middle West.” At no previous period in the history of the world has there been so rapid and

productive an evolution of educational forces as this period has witnessed, and it will not escape notice that it has largely been a development of methods and appliances for the study of science, pure and applied. No sketch of the origin, growth and present condition of the schools of science and engineering in the United States would be complete without reference to the Johns Hopkins University, an institution which, although giving little attention to applied science and technology, has been a very large factor in determining the character and methods of instruction to which these schools owe their success. Although of comparatively recent institution, it is impossible to overestimate its influence upon higher education, and especially is this true in all things relating to science. There is scarcely a college faculty that has not been enriched by the presence of one or more of its graduates, bringing with them at least something of the spirit of that institution, its respect for exact scholarship and regard for scientific truth. For the schools of engineering and technology in the United States are, and are intended to be, something more than a mere avenue leading to increased money-making power. They are intended to fit for the responsibilities of citizenship, and, if worthy of the name, their methods of instruction are such as to cultivate independence of thinking and personal responsibility in judgment. Nor are they deficient in that intellectual discipline and culture which constitute a liberal education. Although not specifically organized for original research, their methods of work naturally lead to and encourage it, and during the past quarter of a century they have contributed generously to the advancement of pure science, to which, however, they must always be in debt. As a whole, they represent one of the most important achievements of an age whose chief glory is found in the increase and diffusion of science and its applications.

Education, Secondary, in America. The history of American secondary education presents three stages of development: First, the colonial period, with its Latin grammar schools; secondly, the period extending from the Revolutionary War to the middle of the 19th century, with the “academy”; and, thirdly, the period down to the present, chiefly characterized by the growth of public high schools.

The influences which most vitally affected the early development of secondary education in America were the example of the “grammar schools” of England and the rising spirit of democracy, which was largely Calvinistic in its

EDUCATION

modes of thought, and kept in touch with Calvinistic portions of Europe.

Early in the history of the colony of Virginia, funds were raised and lands set apart for the endowment of a Latin grammar school. But these promising beginnings were swept away by the Indian massacre of 1622, and the school seems never to have been opened. The town of Boston, in the Massachusetts Bay Colony, set up a Latin school in 1635, which has had a continuous existence down to the present time. This school was established by vote of the citizens in a town meeting. It was supported by private donations and by the rent of certain islands in the harbor, designated by the town for that purpose; a town rate seems to have been levied when necessary to make up a salary of \$244.50 a year for the master. Other Massachusetts towns followed the example of Boston. School fees were commonly collected. A town rate, which was depended upon at first only to supplement other sources of revenue, gradually came to be the main reliance; and by the middle of the 18th century most of the grammar schools of Massachusetts charged no fee for tuition. Latin schools were early established in Connecticut; one at New Haven in 1641, and one at Hartford not later than 1642. A notable bequest of Edward Hopkins, sometime governor of Connecticut Colony, available soon after the middle of the 17th century, was devoted mostly to the maintenance of Latin grammar schools in Hartford and New Haven, and also in the towns of Hadley and Cambridge in Massachusetts. The Dutch at New Amsterdam opened a Latin school in 1659, continued for some years after the colony passed under English rule. Secondary schools were established in Pennsylvania in the latter part of the 17th century. One of these, the William Penn Charter School at Philadelphia, has continued down to the present day. King William's school at Annapolis was erected by the legislature of Maryland in 1696, and similar schools were established in different sections of the same colony. The 18th century saw schools of like character opened, partly by legislative enactment, partly by private initiative, in these and in the remaining colonies. Some of the number, like the University Grammar School in Rhode Island and the Free School at New York, were forerunners of the accompaniments of colonial colleges. In the organization of colonial systems of secondary education important beginnings were made. In 1647 the colonial legislature of Massachusetts decreed that an elementary school should be maintained in every town of 50 families; and that in every town of 100 families there should be a grammar school, in which students might be fitted for the university. This provision was copied by the colonies of Connecticut and New Hampshire, and in Connecticut the provision was afterward changed to require a grammar school in each county town. These New England colonies maintained and enforced such provisions down to and after the Revolution. Maryland also established by law a system of county grammar schools. When the colonies were transformed into States, after the Declaration of Independence, the systems of schools in the four colonies mentioned were continued with little change, but no other of the 13 States had anything that could be called a system of public instruction.

The chief emphasis in these colonial schools was laid on preparation for the college entrance examination, and the requirements for admission to college determined their course of study. The colonial grammar schools accordingly taught Latin, a little Greek, religion, and little else.

Both grammar schools and colleges were intended especially for the directive and professional classes, and had little connection with such elementary schools as there were. In Massachusetts, towns which maintained grammar schools were not required to maintain reading schools. Sometimes pupils were taught to read in grammar schools. But the grammar school teachers objected to this burden; and the mixing of the two grades of instruction in one school was recognized as an evil. The grammar schools exercised a kind of selective function, discovering latent capacity for the higher studies and starting talented youth on the way to college. Those who showed capacity of a lower grade or of a different sort received little attention or encouragement.

As we approach the Revolutionary period, we find new social conditions giving rise to a new order of schools. With the growth of sectarian differences, there appeared a decided tendency toward the separation of governmental from ecclesiastical affairs, and thus the position of educational institutions was disturbed. This change lessened the prestige of colonial systems of education among the adherents of the religious denominations, and a growing distrust of the colleges appeared among those who were most in accord with the secularizing tendency of the time. The old grammar schools were weakened by these influences, and in their stead there grew up a new type of secondary school, commonly known as the academy.

Both the name and the character of the new institution were suggested by precedents in England, where Dissenters were excluded from grammar schools and universities. In the latter part of the 17th century the non-conformist bodies first established "academies," schools in the main of secondary grade, which, however, undertook to prepare candidates for the non-conformist ministry.

The fame of the English academies seems to have influenced the thought of the American colonists in the matter of public education; first the strong theological bent of their English prototypes reappeared in the new American schools; and then the resemblance was more obvious in the wide range of studies offered, for the English academy had been more practical and technical than the university. But the American academies soon came to have a well-defined character of their own, apart from any conscious imitation of English models.

In 1726, a school for classical and theological studies was established by a Presbyterian minister at Neshaminy, in Pennsylvania. It was commonly known as the "Log College," as its home was a building made of logs. This school in the wilderness was the centre of deep and widespread interest in classical studies as well as in the religious life. It sent out large numbers of zealous pastors and teachers, who established "log colleges" all over the highlands of the middle and southern colonies. The Neshaminy Log College itself was later incorporated with what is now Princeton University.

EDUCATION

Through the efforts of Benjamin Franklin, a school was established at Philadelphia, legally incorporated as an academy in 1753, and probably the first institution in America formally designated by that title. It was under the control of a self-perpetuating board of trustees. A fund raised by private subscription for its establishment and maintenance, was supplemented by a grant from the city treasury and by tuition fees, which were remitted in the case of those unable to pay. This academy organized in three departments or schools; namely, the Latin, the English, and the mathematical, put little stress on the theological element and much on English language and literature, and the mathematical sciences. The school ultimately developed into the University of Pennsylvania. Within two or three decades after the founding of this school at Philadelphia, a number of schools somewhat similar in character, and some of them bearing the name academy, were established in the middle and southern colonies. In New England the two Phillips academies, one at Andover in Massachusetts and the other at Exeter in New Hampshire were incorporated in 1780 and in 1781, respectively. The influence of these two schools extended to remote States, especially in the growing West; and they still rank among the strongest and most influential secondary schools.

Soon after the close of the Revolutionary War, new State systems of education began to be established, in which special provision was made for secondary schools. The University of the State of New York, erected in 1784, is a notable example of the strong influence which French thought then exercised in American affairs, as it realized the conception of a university put forth by Diderot and others of the great French writers of the latter half of the 18th century. It embraced the whole provision for secondary and higher education within the State, with the exception of schools of a purely private character. Its control was vested in a board of regents, consisting of the governor and the lieutenant-governor, *ex officio*, and 19 members elected by the State legislature. The reorganization of 1787 accordingly made the board of regents distinct from the board of trustees of Columbia College, with which it had been identical. This "university" exercised great influence on later systems; and in Georgia, by an Act, passed in 1785: "All public schools instituted, or to be supported by funds or public moneys in this State, shall be considered as parts or members of the university"; and in the territory of Michigan, an act was passed in 1817 instituting a university of imposing character. The latter establishment existed mainly on paper, and the act incorporating it was repealed in 1821. The Georgia "university" also never amounted to much. But although the comprehensive type of university organization was not widely adopted, there was a general desire in the early part of the 19th century to establish complete and well-rounded systems of public instruction. The legislature of Tennessee declared in 1817 that, "Institutions of learning, both academies and colleges, should ever be under the fostering care of this legislature, and in their connection with each other form a complete system of education." Even more significant is the provision of the constitution of Indiana, adopted in 1816, that, "It shall be

the duty of the general assembly, as soon as circumstances will permit, to provide by law for a general system of education, ascending in regular gradation from township schools to a State university wherein tuition shall be gratis and equally open to all." For the most part, however, actual State agency in secondary education was as yet limited to the subsidizing of privately managed academies. In Massachusetts, the provision for grammar schools under town control was continued after the colony became a State, but the law was so changed that only the larger towns were left subject to this requirement. At the same time academies established by private initiative were endowed by the legislature with grants of public lands. In Kentucky, the State legislature granted 6,000 acres of public lands to an academy in each county. In Pennsylvania, colleges and academies received financial aid from the State for many years, culminating in 1838 in a general State system of educational subsidies. Five years later, such aid was discontinued. In other States, the granting of State subsidies, in money or in lands, to secondary and higher schools, was customary for many years. For the most part, there is but little system or consistency observable in the distribution of such aid; and the State-aided institutions were not subjected to any sort of State control.

The type of secondary school which grew up under these conditions demands closer consideration. The old academies were generally endowed institutions, organized under the control of self-perpetuating boards of trustees or of religious bodies, established to serve the need of a wide constituency and not merely of a single community, and often located in small country places. Many of them made provision for boarders as well as for day pupils. They were not intended in any exclusive sense for the training of future members of the learned professions, although many of them developed into preparatory schools. In the western States preparatory schools attached to colleges were commonly called "academies." But such was not the earlier purpose of the academies, which were largely schools for the middle classes, and answered to a growing desire after learning for its own sake, or for the increased efficiency it would give in other than professional pursuits.

Their training was more "practical" than that of the colleges, wider and more liberal than that of the grammar schools, or of some of the colleges. They laid new stress on the study of the English language, together with grammar, rhetoric, and public speaking. They taught mathematics, often including surveying and navigation; began the study of natural science, especially of natural philosophy (physics), of which astronomy constituted an important division; gave courses in geography, ancient history, English and above all American history, French often and German seldom. Latin and Greek were the substantial core of the instruction offered. In the earlier days, the course of study was not well defined. In English, Latin, and mathematics, a good degree of continuity of work was apparently maintained, but in others, classes were formed at irregular periods, because of the exigencies of rural life which demanded that certain courses be confined to a short winter term not interfering with farm labor. When finally definite courses of study

EDUCATION

were laid out, they varied in length from three to four or five years. Parallel courses were offered. That including classical studies and covering the required preparation for admission to some college was commonly regarded as the standard course of the school. With this might be found an English course. Afterward a scientific course was often provided.

Many of these schools were established by religious bodies. Catholic secondary schools began to appear in this period, established by the several teaching orders. The Society of Jesus founded institutions of secondary and higher education in the United States after the Revolutionary War; the Brothers of the Christian Schools opened their first school in America at Montreal in 1838; soon after set up establishments within the United States, at Baltimore and New York, and followed these elementary schools with secondary courses; and besides many conventual schools for girls were established, which drew a large clientele from other than Catholic families. The academies established by Protestant bodies usually terminated their formal connection with ecclesiastical societies upon their legal incorporation. The religious instruction which they carried on concerned itself for the most part with the broad underlying principles of Christianity, so that the non-Catholic academies, even such as had arisen from the initiative of religious societies, tended toward the non-sectarian character which has been more fully exemplified in the public schools of later times.

The grammar schools had been exclusively for boys. Such was the case with many of the academies. But others were coeducational, and there grew up also a large number of academies for girls, which were all too often weighed down with the title of "female seminary." The last two prepared the way for two types in higher education, appearing in the fourth decade of the 19th century, namely, the coeducational college and the college for women exclusively.

The academies broadened the intellectual horizon of families and communities, and reinforced the protest which was arising against the narrow curriculum of the American colleges. In the absence of special schools for the training of teachers, the better elementary schools were for a long time in the hands of academy graduates. Special classes were organized in New York and Pennsylvania academies for instruction in the art of teaching, and a seminary for teachers was opened in connection with the Phillips Academy at Andover. When State normal schools began to be established, in Massachusetts in the year 1839, suggestions for their organization and management were drawn from this seminary and from the current practice of the academies.

In the early part of the 19th century, there appeared a strong demand for schools under the exclusive control of the State. The Calvinistic view of the civil power had apparently prepared the way for State agency in education, and the steadily advancing separation between Church and State kept alive the question as to the relation of the schools to both. The well-established theory that the State should grant charters to colleges, authorizing them to manage their own affairs under close corporations, with incidental aid from the State in the shape of gifts of land or money, was long applied to

secondary education as well. The first step in the establishment of public secondary schools was taken by the larger towns and municipalities, under the lead of Boston, where in 1821 was established an "English classical school," which soon took the name of "English high school," imitating the style of the Edinburgh High School, from which the new Boston school differed in not including the ancient languages in its curriculum, and in not employing the monitorial method of instruction. Its course was three years, embracing English language and literature, mathematics, navigation and surveying, geography, natural philosophy (including astronomy), history, logic, moral and political philosophy. Latin and modern languages were added afterward and the course extended to four years. Students were received into the high school from the elementary schools of the city, but at first were not prepared for admission to college, that being the function of the Latin school. But with the addition of foreign languages to its course of study, the English high school fitted its students for admission to certain higher institutions.

Other Massachusetts towns followed the lead of Boston in this matter. Philadelphia, in 1838, established the Central High School, under special authorization from the Pennsylvania legislature. Baltimore followed, with the establishment of a "city college." Providence opened a public high school in 1843. Hartford, in 1847, transformed her old grammar school into a school of the newer type. New York opened a "free academy" in 1848, the name of which was afterward changed to the College of the City of New York. This school was established in accordance with a special act of the State legislature, ratified by vote of the people of the city. Later growth was rapid and widespread, although the movement encountered hostility from those who regarded the academy as the final or best solution of the problem of public secondary education, and from those who were opposed on principle to the recognition of secondary education as a proper field for governmental agency. The legal questions involved in this latter contention were settled by the supreme court of Michigan, in what is commonly known as the "Kalamazoo case," the decision being: "Neither in our State policy, in our constitution, nor in our laws do we find the primary school districts restricted in the branches of knowledge which their officers may cause to be taught, or the grade of instruction that may be given, if their voters consent, in regular form, to bear the expense and raise the taxes for the purpose."

As early as 1798, Connecticut authorized the opening of higher schools by the local authorities ("school societies"). In Massachusetts, the law requiring grammar schools in the towns was so far weakened, in 1824, that towns having a population of less than 5,000 were allowed to substitute therefor an elementary school. But two years later it was enacted that every town having 500 families should provide a master to give instruction in history of the United States, bookkeeping, geometry, surveying, and algebra; and every town having 4,000 inhabitants, a master capable of giving instruction in Latin and Greek, history, rhetoric, and logic. Iowa adopted a provision in 1849 expressly permitting the adding of higher grades to the public

EDUCATION

schools; and in 1858 authorized the establishment of county high schools. In New York, systematic grading of the schools went steadily forward; and the "academic departments" of these schools, corresponding to the high schools of other States, formed a part of the University of the State of New York and received financial aid from the literature fund. In Maryland, the county academies, which had displaced the grammar schools of colonial days, continued for many years to receive financial aid from the State, and only in comparatively recent times were merged into a State system of high schools.

We have seen that by the middle of the 19th century the academies were now *par excellence* the preparatory schools of the country, and that the growth of high schools had taken away from them the character of the ordinary provision for secondary education. Many of them declined as the high schools advanced; many were given over to the communities in which they were conducted and became high schools, under public management; and those that survived laid more and more stress on their function of preparing for college. While the high schools are for day pupils only, the academies are generally boarding schools. At the first there was an organic connection between the high schools and schools of elementary grade, but a recognized gap between the high schools and institutions of higher learning, the earliest high schools being intended specifically for those who were not preparing for college. But there soon appeared a disposition on the part of the public school authorities to close up this gap, and studies regarded as distinctively preparatory to college were introduced into high school courses.

Even when the high schools had begun to prepare their more favored students for college, the connection between the secondary and the higher institutions was not so close as was desired, because of the inherent differences between the college and the secondary system, especially in the East where few universities were under State control. For a long time the most powerful single agency affecting the course and the methods of instruction in the better high schools, as in the academies, was the entrance examinations of the several colleges.

Thus the college examination became the chief end and aim of much of the work in secondary schools, and there appeared a marked tendency to substitute a cramming process for real educational procedure. The attempt to correct this evil has taken several different directions. One of the earliest and most noteworthy attempts at its solution is the so-called accrediting system, introduced by the University of Michigan in 1871. Under this system, the university admits to its freshman class, without examination, such graduates of approved secondary schools as are especially recommended for that purpose by the principals of those schools. It depends upon a purely voluntary agreement between the secondary schools and the higher institutions, so that the school rather than the individual is examined; and the inquiry relates chiefly to the vitality, intelligence, and general effectiveness of the instruction. The highest grade of efficiency in university inspection is found in such a system as that maintained by the University of California,

where the accrediting of schools is in the charge of a committee of the academic senate, some of whose members visit every year all secondary schools within the State which apply for accrediting.

The purpose of a well-considered accrediting system is not to provide a means whereby applicants for admission to college may escape a dreaded examination, but to encourage and build up strong and efficient schools of secondary grade.

The disadvantages of the system are that it tends to foster a disposition to evade all tests of accurate scholarship in the shape of definite examinations; that it entails a heavy burden upon the higher institution; and demands large expenditures of money and of the time of university instructors. In the University of California, the actual cost in money for the traveling expenses of the inspectors is about equal to the salary of an assistant professor and the aggregate of the time required each year by all departments for the purposes of examination of schools is not far from three full academic years. The accrediting system cannot be regarded as a final solution of the problem with which it deals, but it marks a great advance, and it is safe to say that its present advantages greatly outweigh its obvious disadvantages.

Parallel with the later development of the accrediting system, there have grown up important voluntary associations of instructors, in which representatives of the colleges meet with representatives of the secondary schools for the discussion of topics of common interest. The parent society of this sort is the New England Association of Colleges and Preparatory Schools, organized at Boston in 1885. This organization prompted the establishment of the commission of colleges in New England on admission examinations, which, by its recommendations, has done much to unify requirements for college matriculation.

The Association of Colleges and Preparatory Schools in the Middle States and Maryland came into existence in 1892. The North Central Association of Colleges and Secondary Schools was formed at Evanston, Ill., in 1895; and the Association of Colleges and Preparatory Schools of the Southern States, at Atlanta, Ga., in the same year. State organization somewhat similar in character are found in a number of the States, as in New York, Ohio, Tennessee, Colorado, Michigan, and both Dakotas. These various societies, through their discussions and recommendations, have exercised a vast influence upon the development of our secondary education.

But the chief landmark in the recent history of this grade of school is the work of the Committee on Secondary School Studies, appointed by the National Educational Association in 1892, and commonly known as the "Committee of Ten." This committee was the outcome of a movement within the national association in the direction of uniformity of college entrance requirements. Not limiting itself to the mechanical adjustment of relations between the high school and the college, this committee proceeded to consider the problem of secondary education from an educational point of view. Nine sub-committees of 10 members each were appointed to prepare reports on the several or-

EDUCATION

dinary departments of secondary school instruction, namely, Latin, Greek, English, other modern languages, mathematics, physics (with astronomy and chemistry), natural history (biology, including botany, zoology, and physiology), history (with civil government and political economy), and geography (physical geography, geology, and meteorology). The Committee of Ten, having secured carefully prepared reports from its sub-committees, and having examined a large number of the courses in actual use in secondary schools, drew up a report which was published by the United States government in December 1893, together with the reports of the several sub-committees. Great stress was laid on the correlation of studies in secondary schools, the unifying of many subjects into a well-knit course of instruction, through the recognition of their numerous inter-relations. The committee would have continuous instruction in the four main lines of language, mathematics, history, and natural science. In particular, they recommended that in the first two years of a four-year course, each student should enter all of the principal fields of knowledge, in order that he may fairly "exhibit his quality and discover his tastes"; and urge the postponement of the beginning of Greek to the third year, in order that the student may not find himself at the bifurcation of the course into classical and Latin-scientific courses, before he is ready, or his advisers sufficiently informed as to his capabilities, to make an intelligent choice. The committee would require in each course a maximum of 20 recitation periods a week; but they would have five of these periods devoted to unprepared work; and would reserve double periods for laboratory exercises whenever possible. With reference to requirements for admission to college, the committee recommend "that the colleges and scientific schools of the country should accept for admission to appropriate courses of their instruction the attainments of any youth who has passed creditably through a good secondary school course, no matter to what group of subjects he may have mainly devoted himself in the secondary school." "A good secondary school course" they describe as consisting of any group of studies from those considered by the sub-committees, "provided that the sum of the studies in each of the four years amounts to 16, or 18, or 20 periods a week,—as may be thought best,—and provided, further, that in each year at least four of the subjects presented shall have been pursued at least three periods a week, and that at least three of the subjects shall have been pursued three years or more."

Since the early days of the academies, it has been customary in many schools to offer alternative courses; one of them classical, the other "modern." Especially within the last 25 years, there has appeared a strong demand that instead of a choice of courses the students be offered a wide range of choice in particular subjects. Several influences have combined to bring about this demand. Teachers have objected to close prescription in high schools when freedom is increasing in the higher institutions. The conviction that the secondary schools should not be merely tributary to the colleges is gaining ground, and the independence of the secondary school carries with it independent responsibility for the supply of the actual educational needs

of the youth attending such a school. It is urged that, since no two students have exactly the same aptitudes, so far as possible, every student should pursue a different course of instruction from every other student. This doctrine substitutes a quantitative for a qualitative consideration of the curriculum. A high school curriculum, under this system, would consist of a fixed number of units of study, to be chosen at will from the whole number of studies taught in the school. Certain utterances of the Committee of Ten have tended to strengthen this quantitative view of the curriculum. In the attempt to reduce this doctrine to practice, certain modifications necessarily enter. The choice of studies cannot be left simply to the immature pupil. Even if other subjects may be given over to absolute freedom of election, studies in English are found to be indispensable in every course. Little by little, other subjects are acknowledged to be essential; until it appears that there is little difference in practical working between a system of parallel courses rendered flexible by the allowing of occasional substitutions, and an adequately supervised elective system.

The latest attempt at an adjustment of the relations of secondary schools and colleges, to the educational advantage of both, is contained in the report of the Committee on College Entrance Requirements, appointed in 1895 by the National Educational Association, and consisting of 14 members, representing the high schools and universities of different sections of the country, under the chairmanship of the superintendent of high schools of the city of Chicago. The first important service rendered by the committee was the preparation and publication of a table showing the actual entrance requirements of 67 representative colleges, universities, and higher technical schools in the United States. The committee's final report, presented at the meeting of the National Educational Association in July 1899, is mainly devoted to the attempt to establish "national units, or norms," in the several subjects taught in the secondary schools as preparatory to the college course. The fundamental problem "is to formulate courses of study in each of the several subjects of the curriculum which shall be substantially equal in value, the measure of value being both quantity and quality of work done." In the determination of these norms, the committee received assistance from several bodies of expert scholars in the several branches of instruction. The American Philological Association proposed courses of study in Latin and Greek; The Modern Language Association of America rendered a like service with reference to the French and German languages; the American Historical Association and the Chicago section of the American Mathematical Society reported on courses in history and mathematics; and the Department of Natural Science Instruction of the National Educational Association presented recommendations relating to physical geography, chemistry, botany, zoology, and physics. These several supplemental papers are published in connection with the committee's report. The committee adopted 14 resolutions, of which the following are of the greatest general significance:

1. That the principle of election be recognized in secondary schools.

EDUCATION

4. That we favor a unified six-year high school course of study beginning with the seventh grade.

6. That while the committee recognizes as suitable for recommendation by the colleges for admission the several studies enumerated in this report, and while it also recognizes the principal of large liberty to the students in secondary schools, it does not believe in unlimited election, but especially emphasizes the importance of a certain number of constants in all secondary schools and in all requirements for admission to college.

12. That we recommend that any piece of work comprehended within the studies included in this report that has covered at least one year of four periods a week in a well-equipped secondary school, under competent instruction, should be considered worthy to count toward admission to college.

Actual courses of study in our secondary schools show great diversity, as this matter is generally left to the discretion of municipal or district boards of education. Owing to the extensive circulation of all sorts of educational publications, however, and the frequent meeting of teachers one with another in educational conventions, there is a surprising approach toward uniformity in the educational provisions found in all parts of the country. High schools may be found having courses ranging all the way from one to six years in length; but the four-year course is the generally recognized standard. Twenty years ago, it was common to find courses weighed down with a large number of subjects, many of them pursued for only a fraction of a year. This was notably true of subjects in natural science; but it is true to a much less extent at the present day. In spite of all assaults made upon the classical studies, it would perhaps be fair to say that in many of the better schools, public as well as private, the classical course is commonly regarded as the standard, from which the other courses pursued in the same school are looked upon as variants.

The differentiation which appears everywhere in our secondary education appears in the erection of special schools for special classes of students. There is separate schooling of boys and girls, in many instances. The report of the United States commissioner of education for 1896-7 showed a total of 5,109 public high schools in the whole country, of which 35 were for boys only, 26 for girls only, and the remainder co-educational. The same report showed a total of 2,100 private high schools, academies, etc., of which 351 were for boys only, 537 for girls only, and 1,212 coeducational. Another special type of school, the evening high school, has been established in a number of our larger cities. These schools have offered very elastic courses of study, suited to the varied needs of their clientele; and have been a great boon to many who have been obliged to work by day after the completion of an elementary school course. In the Southern States there is further separation between white and colored children, although the latter class of course do not bulk largely in secondary education.

As to manual training schools, St. Louis in 1879 established such a school in connection with Washington University, and within a few years similar schools were established in Baltimore, Chicago, Toledo, New York, Philadelphia,

and other cities. In these schools, the idea of manual training for the purposes of general culture was usually uppermost, their projectors disclaiming any intention of establishing schools for the teaching of trades. More recently trade schools have been established in the largest cities, but for the most part under private initiative and control. The commercial spirit of this country finds expression in the frequent appearance of such subjects as bookkeeping and commercial arithmetic in general courses of study. Special schools for distinctively commercial training are usually private ventures. These are found in great numbers in all parts of the country, generally going by the name of "commercial college" or "business college." The business high school in Washington, D. C., may be mentioned as one illustration of the serious interest which has begun to appear in this side of secondary instruction. See EDUCATION, COMMERCIAL.

One movement should be mentioned which is part cause and part result of the increased attention which is now paid to problems of secondary education, in themselves considered. Reference is made to the study of the several aspects of adolescence, as a stage in the mental development of individuals. Secondary education being essentially the education of adolescents, whatever throws light upon the peculiar psychology and natural history of this period of youth is of value to the educator. Many studies of particular phases of adolescent development have been made within the past few years, under the stimulus of investigations begun at Clark University. These studies are as yet fragmentary; and they cannot be said to have led to well-defined reforms. Yet their influence has been manifest in the general tone and spirit of secondary education. They have prompted to a more sympathetic treatment of our youth in their time of spiritual reconstruction; to a better appreciation of the difficulties attending the passage from the intellectual dependence of childhood to the individual convictions of manhood and womanhood. They have led to a more careful observation of individual differences of development, and have strengthened the demand for greater freedom in both courses and methods of instruction.

Methods of instruction in all secondary school subjects have been profoundly influenced of late from the side of the natural sciences. Laboratories have become common in high schools and academies. College entrance requirements have been extended to include laboratory work in physics, and, in some instances, in chemistry or in the biological sciences. In these laboratories, students perform representative experiments in the science they are pursuing, under the guidance and subject to the criticism of the instructor. These experiments are commonly regarded as illustrative of or preparatory to the statement of principles in a text-book. The "method of re-discovery" has influenced the practice of the schools; yet there are probably few school laboratories in which the students are expected to re-discover on their own account the laws of physics or chemistry, or of any other of the sciences. A fine blending of discovery, verification, and correction seems to be the ideal of our best teachers of natural science. Much stress is laid on the accurate recording of observations and experiments. The students' note-books serve as one of the chief tests of the excellence of their

EDUCATION

work. This is a great advance upon the prevailing method of a generation ago, when the textbook was the main reliance in school instruction, even for classes in the natural sciences. A like change appears in the treatment of other branches than the natural sciences. The attempt is now made to put the student in touch with first-hand materials of knowledge; and to guide and stimulate him to the end of making over these crude facts into real knowledge for himself. This procedure seeks to give full recognition to both the ideal and the sensuous elements in knowledge, and indicates some appreciation of the fact that the ideal element to be truly ideal must be supplied by the active agency of the student's own thought, exercised upon the products of his own experience. In the practice of the schools, we find these principles applied, for example, to the teaching of history. Although text-books are not dispensed with, the effort is made to give the student some acquaintance with the sources of historical knowledge. In the study of literature, less attention is paid to historical summaries than was formerly the case, and more time is devoted to the study of literary masterpieces. In grammar and rhetoric, the study of principles is closely connected with the study of passages from literature which embody those principles in living forms; and with composition exercises upon topics which invite free expression. In modern languages, facility in conversation is not commonly sought, but the ability to read the languages readily and with understanding, and to enter into an appreciation of their literatures, is the end chiefly striven for, and grammar is studied, on the whole, less abstractly than formerly, and more in its actual embodiment in literature. Greater effort is made now than a generation ago to secure a reading knowledge of the ancient classics. There is much difference of opinion among leading teachers as to the proportionate attention to be paid to "sight reading"; and as to the value of the inductive method in the mastery of grammatical principles; but actual practice seems to be tending slowly toward a middle course, which retains much of the old-time thorough discipline in Latin and Greek grammar, but brings this training into more vital connection with the study of classic literature. The question of approaching Attic through modern Greek has been warmly discussed, but the proposed change finds little, if any, acceptance in actual practice. In mathematics, much stress is laid upon the original demonstration of theorems, particularly in plane and solid geometry. Much stress is put upon the use of accurate language in mathematical demonstrations, and, more generally, on the need of more careful and accurate English expression in all school exercises. The attempt to teach English expression, oral and written, wholly through the medium of instruction in other branches does not promise well; but there is a growing recognition of the fact that all teachers must have at least some share in the responsibility for such instruction.

The moral influence of secondary schools is undoubtedly the most important topic to be considered in this paper, but it is at the same time the most difficult to reduce to accurate statement. The religious background of moral instruction has already been referred to. It should be added that even in public high schools, from which all instruction in sectarian dogmas is

strictly excluded, there is not uncommonly found a pervasive religious atmosphere, an influence emanating from the personal character of the instructors. In many of these schools, it is still customary to open the daily session with the reading of a passage from the Bible or the repetition of the Lord's prayer; or with the singing of a devotional or patriotic hymn. In some schools, elementary ethics is taught, but this is unusual, and moral force depends mainly on the personal influence of the teachers, on the government of the school, and on the relations of the students one with another.

Some subjects of instruction offer especial advantages as regards the formation of high ideals of conduct. The teaching of literature, and particularly the literature of the mother tongue, is found to be of great value in this respect—the more so, doubtless, when untimely moralizing is dispensed with, and noble sentiments are permitted to make their appeal through the charm of their artistic presentation. Choice works of plastic and pictorial art are rapidly finding their way into our school rooms, and are expected to accomplish their mission by their mere presence; or to reinforce the æsthetic side of instruction in literature and in drawing. History is probably, on the whole, the most neglected of the main lines of study in secondary schools; and the moral loss resulting from such neglect is serious. Greek and Roman history is commonly taught, at least in classical courses; but too often in a scrappy and inadequate fashion. Later European history receives some attention. The history of the United States is, perhaps, the most seriously slighted of all. The reason for this seems to be that the history of our own country is studied in the grammar schools; and it is only beginning to be emphasized by the colleges as an admission subject.

In the government of our best secondary schools, the relations of teachers and students are comparatively informal, and there is little consciousness of official or artificial barriers between them.

Some interesting and successful experiments have been made in the organization of regular systems of self-government among students. Under any system of government, the social life of the school is the chief teacher of morals. The fact that tuition in these schools is free to all, helps to bring about this result. It is unnecessary to point out the numberless bearings of this democratic spirit in the schools upon the pupils who are subject to its influence. There is undoubtedly a growing disposition among families of wealth and high social position, to send their children to private schools. This disposition is, however, by no means universal.

The social organization of the students in high schools and academies is much alike. The instinct of association is strong and finds expression in clubs, leagues, societies, and fraternities. The several classes are commonly organized, with class officers, and have occasional gatherings of a social character. The offices of the highest class in school are sought for with keen competition. Athletic associations, football and base-ball clubs, and the like, are usually maintained, and several schools often join in an athletic league. Debating clubs and other literary societies are maintained with much interest. Contests in debate with neighboring schools call

EDUCATION

forth a spirit of emulation like that displayed in athletic struggles. Musical organizations are among the most pleasing of school societies. Annual publications by successive classes present a record of the varied interests of the larger schools. Besides Greek-letter societies, formed after the fashion of the colleges, there are sometimes voluntary associations for religious culture and observance maintained by the students. All of these organizations are commonly under the immediate control of the students themselves. The completion of the course of study in a secondary school is celebrated in public with "graduation" exercises and the conferring of diplomas upon the members of the class. The graduates of a flourishing school usually organize in an alumni association.

A committee of the National Educational Association—the so-called Committee of Fifteen on elementary education—reported in 1895, among other topics, on the training of teachers for secondary schools. This committee declared that, "The degree of scholarship required for secondary teachers is by common consent fixed at a collegiate education." They proposed a course of special training for such teachers, consisting of instruction during the senior year of the college course in psychology, methodology, school systems, and the history, philosophy, and art of education; and a graduate year of practice in teaching, under close supervision, supplemented by advanced studies in educational theory. This proposal is far in advance of common practice or requirement. Very few of the American States make any specific requirement for the high school teacher's certificate beyond that for a license to teach in the elementary schools. But in many secondary schools teachers rarely obtain employment unless they are college graduates; and there are large sections of the country in which common usage is rapidly tending in this direction. The most of the leading universities and some of the higher normal schools are devoting especial attention to the professional training of teachers for schools of this grade. A Massachusetts report for the year 1897 shows that one per cent of the high school teachers then employed in that State were graduates of scientific schools, 13 per cent of normal schools, and 66 per cent of colleges. In the State of New York, in 1898, 32 per cent of the teachers in secondary schools (not including principals) were college graduates, 39 per cent were normal school graduates, and 19 per cent were high school graduates. Of the principals, 51 per cent were college graduates, 35 per cent normal school graduates, and 8 per cent high school graduates. These figures include private academies as well as public high schools. They include also one-year, two-year, and three-year schools, as well as fully developed high schools and academies. An inquiry into the preparation of teachers in the secondary schools of California, in October 1897, showed that of the teachers then employed in the public high schools of the State 59 per cent were college graduates.

The several States have been slow to organize general systems of secondary schools. But a few have made considerable progress. The early history of secondary schools in Massachusetts has already been told. This State is the foremost in the Union in the universality of its provision for secondary education. Every

"town" (township) in the State is required by law to provide free high school tuition for all students who are prepared for that grade of instruction. Inasmuch as the whole State is divided into towns, this means that free secondary education is offered to every child in the commonwealth. Of the 353 towns in the State, 185 are required by law to maintain high schools; 70 others maintain high schools, though not required to do so; and those not maintaining such high schools are required to pay the tuition fees of qualified students within their limits who go elsewhere for high school instruction. The poorer towns receive help from the State in paying for tuition in outside schools. The high schools must offer a four-year course, of 40 weeks a year, and they must prepare pupils for the State normal schools, and for higher scientific schools and colleges. The organization of the University of the State of New York has been mentioned. It presents the most thoroughly organized State system of secondary education yet developed on American soil. All incorporated secondary schools in the State and all other secondary schools which may, after official inspection, be admitted to membership by the regents, are institutions of the university. Of the six departments into which the work of the regents is divided the college and the high school departments are under one department director, assisted by nine inspectors of schools and by a large staff of examiners. The regents distributed in 1898 a total of \$209,250.48 in State funds to the secondary schools of the State. The method of distribution is as follows: (a) \$100 is allotted to each school approved by the regents, without regard to its size or special attainments. (b) One cent is allowed for each day's attendance of each student in such schools; provided that each student so counted must hold a "regent's preliminary certificate" for admission to the school, or the school must be approved by two university inspectors, as having a higher entrance requirement than the minimum prescribed for the preliminary certificate. (c) The State duplicates the amount raised by the schools for the purchase of approved books and apparatus up to the sum of \$500 a year for any one school. (d) Grants are made on the basis of credentials obtained by pupils in the school who pass the regents' examinations—a method of "payment by results." In 1898, of the money distributed by the regents to secondary schools, about 25 per cent came under item (a); 22 per cent under item (b); 19 per cent under item (c); and 34 per cent under item (d). The regents' examinations are held three times a year. The diplomas issued by the regents to graduates of secondary schools are accepted by Cornell University and by other institutions of higher education in the State, in lieu of entrance examinations in the subjects which they cover. A syllabus is issued by the regents for the guidance of instruction in university institutions. There is free consultation between the officers of the university and the instructors in the schools with reference to the contents of this syllabus. An annual university convocation, in which the representatives of all divisions of the university meet for public discussion, forms one of the notable educational gatherings of the country.

In Maryland, a law of the year 1865 swept away the old academy system, and substituted for it a system of county high schools. This radical

EDUCATION IN LATIN-AMERICA

change was followed by a reaction. Later legislation took a middle course. A law enacted in 1872 provided for the establishment of high schools in the several counties, to be under the control of the boards of county school commissioners, or of district boards appointed by them. Each of these high schools must be "visited and examined annually by the principal of the State normal school, or a professor thereof," and must also be visited once in each term by the county examiner. The support of these high schools is provided for by the county school commissioners, who set apart for that purpose a portion of the ordinary school funds received from the State and the county. About 20 academies continue to receive direct donations from the treasury of the State.

In Indiana there is virtually a system of university accrediting of high schools, the administration of which has been turned over to the State Board of Education. In July 1873 the board of trustees of Indiana University adopted a resolution to the effect that a certificate "from certain high schools" should entitle the bearer to admission to the freshman class. In August of the same year, the State Board of Education adopted plans under which the high schools which were worthy of such recognition should be designated and commissioned. In 1888 the following order was passed: "That hereafter no high school commission be granted except on a favorable report in writing, to be made to the State Board of Education, by some member of the State Board, who shall visit the high school in question as a committee of the State Board for that purpose. That all the high schools now in commission be visited by committees of the board as soon as may be, and that the present list be modified by the reports from such visitation. That in case of change of superintendent in any commissioned high school, the commission then existing shall be in force until a visitation shall be made by a committee of the State Board." By such simple means and without specific legal enactment, an important system of high schools has been built up. These schools rest upon a statutory provision authorizing local school authorities to provide for the teaching, not only of the elementary branches, in English, but also of "such other branches of learning and other languages as the advancement of the pupils may require." They are supported in the same manner as the elementary schools.

The Wisconsin State system of free high schools was established in 1875. It provides for the maintenance of high schools by towns, incorporated villages, cities, or school districts or sub-districts containing incorporated villages or two-department graded schools within their limits. Two or more adjoining towns, or one or more towns and an incorporated village, may unite in establishing and maintaining a high school. These schools are managed by local high school boards, commonly identical with the boards for elementary schools. They are supported primarily by local taxation; but a district is entitled to receive from the general fund of the State a sum not exceeding one half the amount actually expended for instruction in the high school of such district, and not exceeding \$500 in any one year, if the school has been kept in accordance with certain requirements prescribed by law, and if the total amount paid from the State treasury for this purpose in any

one year does not exceed \$50,000. Such a school is under the direct inspection and oversight of the State superintendent. To receive State aid, a school must establish and maintain a course of study approved by that official, and must be taught by teachers whose certificates he has approved. An effort has been made in Wisconsin to encourage high schools in the less thickly settled portions of the State. But it has been found difficult to promote the general establishment of such schools by other units of civil administration than those which establish and maintain elementary schools. In Wisconsin the elementary schools are governed and supported by district school authorities, and not by township boards.

Minnesota may be taken as another type of secondary school control as that State has maintained a State system of high schools since 1881. At the head of this system stands the State high school board, which appoints a high school inspector and a graded school inspector. Any public high school in the State may become a State high school, and is then entitled to receive from the State the sum of \$800 annually. To be a State high school, it must admit students of either sex from any part of the State without charge for tuition, must provide a course of study covering the requirements for admission to the University of Minnesota, and must be subject to the State rules and open to inspection. The State high school board conducts a written examination of classes in the schools twice a year. Students who successfully pass such examinations receive certificates for the subjects so covered; and these certificates are accepted by the university and the normal schools of the State in lieu of entrance examinations in the subjects specified. The taking of this State examination is ordinarily optional with the school; but the State board may require a school to take an examination as a part of the annual inspection. Perhaps the most significant thing about the Minnesota system is the encouragement it gives to high schools in the smaller towns. Communities all over the State tax themselves freely to supplement the bounty distributed by the State board.

Several other States have made marked advance within the past few years in the direction of improved systems of secondary schools, improvements gained through the untiring efforts of devoted friends of education.

ELMER ELLSWORTH BROWN,

Prof. of Education, University of California.

Education in Latin-America. The peculiar nature of the problems in the field of education which the Latin-American republics have been called upon to solve may be shown most conveniently if we consider, (1) the experience of Mexico, and (2) that of Brazil. Characteristic differences in the educational systems of other Latin-American countries are mentioned where the context serves to explain them—that is, in the articles dealing generally with the history and institutions of those countries. In Mexico, subsequent to colonial legislation the first law on the subject of education, in 1823, was based upon liberal principles and contained an excellent plan of study for use in public schools; it provoked a revolution, however, by appropriating some real estate belonging to the Church, suppressing the clerical

EDUCATION IN LATIN-AMERICA

university, and exempting public education from the control of the clergy. The clerical party succeeded in re-establishing the university under direction of the clergy and restoring to the Church its confiscated property. Wars, civil and foreign, and the undetermined relation of the States to the central government, stopped or hindered educational progress, but in 1843 the government established uniform methods of teaching and a graded system of classes in schools. An effort was made in the same year to centralize the management of the educational system in the city of Mexico. Three years afterward the States resumed their proper share of authority in this matter. Between this time and 1857 the country was distressed by revolutions, dictatorships, and the war with the United States which resulted in the loss of more than two fifths of the Mexican territory; but when the constitutional government was established (1857) the educational law of 1843 was restored. In 1861 Ramirez, minister of justice, secured the passage of another law on this subject, liberal in spirit like that of 1833. War with France (1862-7) made it impossible to carry out the provisions of that law; in December 1867, however, the establishments for secondary instruction were reopened, and an effort was made to improve the primary schools and to bring the methods of teaching into harmony with republican principles. The privileges of education were, by the law of 15 May 1869, extended to all social classes, and primary instruction was made obligatory in the federal district and territories. Thus we find that the triumph of liberal theories was preceded by a contest which lasted for 36 years, at least. "The results of this triumph," as Mr. Hilder well says, "have been the complete separation of church and state, universal religious toleration, a constitution based on the broadest republican opinions, a free press, and free schools." Meantime the great mass of the people had remained ignorant and untrained. The task of the government was therefore exceedingly difficult. A plan hopefully formulated in 1873 could not be carried out; in fact, the practical device for producing an impression upon the millions of utterly indifferent common people appears first in a law of 1888 requiring all persons having control of minors to *prove* that the children in their care had received the necessary primary education; the penalty for violation or neglect of this order being a fine (10 cents to \$10) and imprisonment for not more than 10 days. In 1889 Baranda, minister of justice and education, called a convention of prominent educators and representatives of the different States of the republic. The convention met in the city of Mexico 28 November, and its sessions continued until 31 March 1890. A second educational convention met 1 Dec. 1890 and remained in session until March 1891. The conclusions reached in these pedagogic congresses were embodied in the law of 21 March 1891, which provides that instruction in the public schools shall be secular and gratuitous, and that primary elementary instruction (obligatory for children of both sexes from 6 to 12 years of age) may be obtained in any public or private school, or from private tutors. In the federal district and territories committees have been formed to see that the law in respect to compulsory education is complied with; in the States, however, "and particularly the less

populous ones, and where the Indians predominate, compulsory attendance, although recognized by law," it is said, "can not yet be enforced." For the uncivilized Indians of remote districts special schools are provided in which the teachers are young members of the same tribes, trained in normal colleges. The government has organized many schools and colleges in which higher education and scientific training may be obtained. The principal institutions are: National College of Engineers and Mining (all classes open to the public, and no fee required either on entrance or at the time of receiving degree or diploma); Medical College; National Medical Institute (established by the government 1888-90, for the study of the flora, fauna, climatology, and geography of the country, and their practical application to the science of medicine); National College of Agriculture and Veterinary Surgery; Commercial College; National School of Fine Arts; National Conservatory of Music; National Law School; National Military College; normal schools for training male and female teachers; National School of Arts and Trades for Men (manual training and a higher education for workingmen); the same for women (founded by President Juarez 1871, for the purpose of improving the social condition of workingwomen and affording them an opportunity to fit themselves for good business positions); National School for the Blind; a school for deaf-mutes; industrial school for orphan boys; La Paz College (for women); Correctional School of Trades and Professions (for the reformation of boys under 18); and the National Library, containing 170,000 volumes, the nucleus of the collection being formed by the books and documents which came into the government's possession through the suppression of ecclesiastical colleges. There are museums in nearly every State, supported by the local (State) governments. The principal cities, Toluca, Morelia, Guadalajara, Guanajuato, Puebla, Merida, and others, have literary and scientific associations, and a score of such societies exist in the federal district. Of these the most influential is El Liceo Hidalgo, which has for its aim the encouragement of native talent. President Diaz stated in his message of 1 April 1895 that there were about 8,000 public schools for primary education in the republic, with 500,000 scholars; that the amount appropriated by the government for educational purposes was about \$3,500,000 per annum; and that in the federal district there were 62 private free schools, and 195 private schools in which pupils paid for their education. The influence of the government's educational policy since 1857 has been very marked, in spite of the difficulties we have mentioned; and the good results are seen especially in the improved intellectual status of women. Mr. Hilder says that "there is now a very large and influential middle class, composed of both Indian and mixed races, which is every year, by the spread of education, gaining accessions from the humbler class"—the latter making good progress under the new order of things.

Brazil was notably unprogressive during the three centuries of her existence as a colony, while her intercourse with the outside world was controlled by Portugal, though an interest in art and letters awoke when the Portuguese court was transferred to South America (see

EDUCATIONAL LAND GRANTS — EDUCATIONAL ORGANIZATION

BRAZIL. King John introduced printing-presses, established schools, and promoted arts and sciences; the country was visited by large numbers of foreigners, including distinguished writers and scholars, and all this tended to improve the manners and enlarge the ideas of the people. Moreover, when the Cortes of Portugal recalled the king (1821), he left his historical library, which became the nucleus of the great public library at Rio de Janeiro. Independence was declared 7 Sept. 1822, and by a decree in October 1823 any citizen was authorized to establish a primary school without obtaining a special license—a radical departure from the old custom of entrusting elementary education to the clergy alone. In 1827 a law was passed authorizing the establishment of public primary schools in all the cities and towns, but little progress was made until 1854, when a thorough reorganization of the school system was effected. During the second half of the century a development has taken place which is certainly admirable; and no one will be disposed to withhold his commendation who reflects that the country was obliged at the same time to deal with such problems as the Paraguayan war, the emancipation of the slaves, and the change in the form of government from monarchy to republic. Under the constitution the instruction given in public institutions is secular, gratuitous (in primary schools), and at the charge of the various States and municipalities. In some of the States primary instruction is compulsory. An excellent standard has been established in primary schools (except those of remote districts, which are decidedly inferior). Pupils are admitted to the first-grade schools from 7 to 13 years of age, and to the second-grade schools from 13 to 15 years of age. There are separate schools for girls, who are admitted to the first grade at the age of 8 years. The course of study in the first grade is: reading, writing, the Portuguese language, arithmetic as far as the rule of three, metric system, elements of geography and history (especially of Brazil), introductory lessons in physical science and natural history, moral and civic instruction, drawing, elements of music, gymnastics and military exercises, manual training for boys and needle-work for girls, and practical lessons in surveying. The number of primary schools in the republic was recently stated to be 7,017, and the number of pupils about 300,000. There are several hundred private schools. Secondary education is provided in the *Gymnasio Nacional* (two establishments thus named in the capital; course of study seven years). National institutions for higher education are: two law schools (those of São Paulo and Pernambuco); two schools of medicine and pharmacy (at Rio de Janeiro and Bahia); the polytechnic school at Rio de Janeiro; the school of mines at Ouro Preto in the State of Minas Geraes; military and naval schools; the National Academy of Fine Arts, Institute of Music, and Museum; and finally the National Library, containing an immense collection of books and maps, manuscripts, prints, and coins.

Educational Organization and Administration. The first white settlers who came to America were from the more civilized European peoples, who had already made some progress in the direction of popular education. The most potent influences upon American civic institutions were English and Dutch. English colleges and fitting schools were maintained for the training of young men of noble birth for places under the government and in the government church, but there were no common schools for all. The Dutch had gone farther than the English; they had just waged a war for civil and religious liberty which had enlarged their freedom and quickened their activities; they had become the greatest sailors and the foremost manufacturers in the world; and they had established the government policy of maintaining not only colleges, but common schools for all. English and Dutch each brought their national educational ideas with them. The English colony in Massachusetts followed the English educational policy; and set up a college to train their aristocracy for places in the state and the church. The Dutch, more dependent upon their government over the sea, at once set up elementary schools at public cost and common to all. In a few years the English overthrew the little Dutch government and almost obliterated the elementary schools. For a century the English royal governors and the Dutch colonial legislatures struggled over the matter of common schools. The government was too strong for the humble people; little educational progress was made. Near the close of that century the government established King's College to educate sons of noble birth and prevent the spread of republican ideas. The Revolution of 1776 changed all. In fighting together for national independence the different peoples assimilated and became Americans in the new sense. They realized that education must be encouraged, and, so far as practicable, made universal under a democracy in which the rights of opportunity were to be equal. But they began to be interested in education because they saw that schools would help the individual and so promote virtue and extend religion. It did not occur to them at first that the safety of the new form of government was associated with the diffusion of learning, for the suffrage was not universal at the beginning of independent government in America. Therefore, it was understood to be the function of parents to provide education for their children. Schools were partnership affairs between people who had children in their care. They apportioned the expense among themselves. But it was soon seen that many who had children to educate would neglect them to avoid contributing to the support of the school. Besides the schools were very indifferent affairs. If they were to be of any account they must have

EDUCATIONAL ORGANIZATION

recognition and encouragement from government. Encouragement was given by official and legislative declarations in their behalf and by authorizing townships to use various surplus funds for the benefit of the schools. It was a greater step for the townships to require parents and guardians to maintain schools, and a still greater one to adopt the principle that every child was entitled to an elementary education, that this was for the safety of the state, that therefore the state was bound to see that schools were provided for all, and that all the property of all the people should contribute alike to their support. Perhaps it was even a greater step to provide secondary and collegiate, and in many cases professional and technical, training at the public cost.

Although there was no educational system in the United States at the beginning of the 19th century, there is now one throughout the country, free and flexible, adaptable to local conditions, and with the elements of a complete and symmetrical system. The parts of this system may be designated as follows:

(a) Free public elementary schools in reach of every home in the land.

(b) Free public high schools, or secondary schools, in every considerable town.

(c) Free land grant colleges, with special reference to the agricultural and mechanical arts, in all the States.

(d) Free State universities in practically all of the southern States and all the States west of Pennsylvania.

(e) Free normal schools, or training schools for teachers, in practically every State.

(f) Free schools for defectives, in substantially all of the States.

(g) National academies for training officers for the army and navy.

(h) A vast number of private kindergartens, music and art schools, commercial schools, industrial schools, professional schools, denominational colleges, with a half dozen leading and privately endowed universities.

This educational system is held in the control of the people, and so far as practicable in the control of local assemblages. In spite of modern tendencies toward centralization of management, the conspicuous characteristic of the system has always been that elementary and secondary schools are largely controlled and directed by each community.

The School District.—The "school district" is the oldest and the most primary form of school organization, and the smallest civil division of our political system. It resulted from the disposition of neighboring families to associate for the maintenance of a school. Later it was recognized by law. It ordinarily accommodates but a few families, and is better adapted to the country than to town or city. The "district system" is in operation in most of the States; in New York there are more than 11,000 and in Illinois more than 12,000 school districts. Their government is the most simple and democratic that can be imagined. It is controlled by school meetings held annually or oftener and composed of resident legal voters, in many of the States including women, especially of property holders. These meetings vote repairs and appliances for the school, erect new schoolhouses, and elect officers, one or more, commonly called trustees or directors, who are required to em-

ploy the teacher and have general oversight of the school. Although much has been said against the district system, it cannot be denied that the system has had much to commend it, for it suits the conditions of country life; makes schools adapted to the thought and wants of the people; educates the people themselves in civic spirit and patriotism; and affords a meeting-place for the people. The district school ordinarily has been as good as a free and primitive people would sustain or could profit by. The teachers have generally been young and inexperienced, but never mere mechanical automata, and as a rule they have proved makers of opinion and leaders of action upon a considerable field. Certainly the work has lacked system, continuity and progressiveness, but the pupils have not suffered seriously, in comparison with the children living in the towns. The district system has sufficed well for them and it is to be spoken of with respect, for it has exerted a marked influence upon our citizenship, and has given strong and wholesome impulses in all the affairs of the nation.

The Township System.—In the first half of the last century the general educational purpose was to perfect the district system; the tendency in the latter half was unmistakably to merge it into an organization covering a larger area, and capable of larger undertakings. The cause of this has been the desire for larger schools, taught by teachers better prepared, and capable of broader and better work, and a purpose to distribute educational advantages more evenly. Accordingly, in most of the States the township system has already supplanted the district organization. The township system makes the township the unit of school government. It is administered by officers chosen at annual town meetings, or sometimes by central boards, the members of which are chosen by the electors of different sub-districts. In any event, the board has charge of all the elementary schools of the township, and of the township high school, if there is one. The board provides buildings and cares for them, supplies the furnishings and appliances, employs teachers, and regulates the general operations of the schools. Of course the township system is much less formally democratic and much more centralized than the district system. It has doubtless produced better schools and schools of more uniform excellence. One of its most beneficent influences is the multiplication of township high schools.

It has many advantages over the district system for a people who are ready for it, and it is a step toward that general centralization in management and greater uniformity of method so manifest throughout the school system of the United States.

The County System.—The southern States, for the most part, have a county system of school administration. This has resulted from the general system of county government prevalent in the southern States and easily traceable to historic causes.

The county system is not constituted identically in all of the southern States of the Union. In Georgia, for example, the grand jury of each county selects from the freeholders five persons to comprise the county board of education; in North Carolina the justices of the peace and county commissioners of each county appoint

EDUCATIONAL ORGANIZATION

such a county board of education; in Florida such a board is elected by the people biennially; and elsewhere a county commissioner or superintendent of schools is the responsible authority for managing the schools of the county. In any case the unit of territory for the administration of the schools is the county, and county officials locate sites, provide buildings, select text-books, prescribe the course of work, examine and appoint teachers, and do all the things which are within the functions of district or township trustees or city boards of education in the northern States.

The City School Systems.—In cities where it is difficult for people to meet to fix the policies and manage the business of the schools, or to choose officers to manage the schools, the State legislatures make special laws for city schools. In some States these laws are uniform for all cities of a certain population, but more often each city has gone to the legislature and procured the enactment of such statutes as seemed suited to the immediate circumstances, so that there is no uniform or general system of public school administration in the American cities. But in nearly every case there is a board of education charged with the management of the schools; these boards differ in constitution and in legal functions in different cities. Usually boards of education are elected by the people, on a general city ticket, or by wards or sub-districts; and either at a general or municipal election, or at special elections. But in the larger cities, the board is appointed by the mayor, or by mayor and city council. In a few instances it is appointed by the city councils. It must be said that there has been much dissatisfaction with the way school affairs have been managed in the larger cities, where there have been many and serious complaints of misuse of funds, of neglect of property, of appointment of unfit teachers, and of general incapacity, or worse, on the part of the boards. All this has come from the amounts of money that are involved and the number of appointments that are constantly to be made. More than \$100,000,000 is paid annually for teachers' wages alone in the United States. People who are needy have sought positions as teachers without much reference to preparation, and the kindly disposed have aided them without any apparent appreciation of the injury they were doing to the highest interests of their neighbors. Men engaged in managing the organizations of the different political parties have undertaken to control appointments in the interests of their party machines. And downright scoundrels have infested the school organization in some places for the sake of plunder. As cities have grown in size and multiplied in numbers the more scandal there has been. But so has the determination of the people strengthened to remedy difficulties.

Especially important is a report of the Committee of Fifteen of the National Educational Association, which closes with the following suggestions:

First. The affairs of the school should not be mixed up with partisan contests or municipal business.

Second. There should be a sharp distinction between legislative functions and executive duties.

Third. Legislative functions should be clearly fixed by statute and be exercised by a comparatively small board, each member of which is representative of the whole city. This board, within statutory limitations, should determine the policy of the system, levy taxes, and control the expenditures. It should make no appointments. Every act should be by a recorded resolution. It seems preferable that this board be created by appointment rather than election, and that it be constituted of two branches acting against each other.

Fourth. Administration should be separated into two great independent departments, one of which manages the business interests and the other of which supervises the instruction. Each of these should be wholly directed by a single official who is vested with ample authority and charged with full responsibility for sound administration.

Fifth. The chief executive officer on the business side should be charged with the care of all property and with the duty of keeping it in suitable condition: he should provide all necessary furnishings and appliances: he should make all agreements and see that they are properly performed: he should appoint all assistants, janitors, and workmen. In a word, he should do all that the law contemplates and all that the board authorizes, concerning the business affairs of the school system, and when anything goes wrong he should answer for it. He may be appointed by the board, but it is preferable that he be chosen in the same manner as the members of the board and be given a veto upon the acts of the board.

Sixth. The chief executive officer of the department of instruction should be given a long term and may be appointed by the board. If the board is constituted of two branches, he should be nominated by the business executive and confirmed by the legislative branch. Once appointed he should be independent. He should appoint all authorized assistants and teachers from an eligible list to be constituted as provided by law. He should assign to duties and discontinue services for cause, at his discretion. He should determine all matters relating to instruction. He should be charged with the responsibility of developing a professional and enthusiastic teaching force, and of making all the teaching scientific and forceful. He must perfect the organization of his department and make and carry out plans to accomplish this. If he cannot do this in a reasonable time he should be superseded by one who can.

In the present scheme the powers of the city boards of education are very broad, almost without limits as to the management of the schools. They do everything but decide the amount of money which shall be raised for the schools, and sometimes do that. Of course these independent and large prerogatives are exceedingly advantageous to educational progress when exercised by good men; but it is not to be disguised that in some of the foremost cities they have fallen into hands which are corrupt, but more often into the hands of men who do not see the importance of applying pedagogical principles to instruction, and who are used by designing persons for partisan, selfish or corrupt purposes. But notwithstanding all hindrances, the issue is being joined and the battle will be

EDUCATIONAL ORGANIZATION

fought out to a successful result. There can be but one outcome. The forces of decency and progress always prevail in the end.

The demands of the friends of popular education in our great cities are for a plan of organization separating legislative and executive functions, putting the interests of teachers upon the merit basis and leaving them free to apply pedagogical principles to the instruction, giving large authority to officers and teachers, but locating responsibility and ousting the incompetent or corrupt.

The States and the Schools.—Since the American school system is supported wholly by taxation, it depends upon the exercise of a sovereign power. The provision and supervision of schools is a power lodged in the State, and the school system has a legal organization peculiar to each State. This dependence upon State authority has developed a system which tends toward the equalization of school privileges within each State. Of the improvement brought about by intervention on the part of the State in local control, there can be no doubt. In many cases State school funds have been created, or large sums are raised by general levy each year, which are distributed so as to give the most aid to the sections which are poorest and most need it. In the State of New York, for example, the cities pay more than \$500,000 every year to the support of the schools in the country districts. Moreover, excellent normal schools and, in the South and West, great State universities are sustained as parts of the State school systems. In 10 universities of the north-central division of States there are more than 20,000 in college and professional courses, and the work is of as high grade and of as broad range as in the oldest universities of the country. These things exert strong influences upon the sentiment of the people and increase their respect for the State authority over schools. The application of State authority to all schools supported by public moneys of course makes them better and more alike. Whims of local settlements disappear. Schoolhouses are better. More is done for the preparation of teachers, and more uniform exactions are put upon candidates for the teaching service. The courses of study are more quickly and symmetrically improved. There is criticism and stimulus from a common centre for all of the educational work of the State. The different States have gone to very different lengths in exercising their authority. The State government has, of course, not been disposed to go farther than the people were willing, for all government is by the people. The thought of the people in the different States has been somewhat influenced by considerations which arise out of their early history, but doubtless in most cases it is predicated upon their later experiences.

All State constitutions now contain provisions relating to popular education. This was not true of the original constitutions of the older States, for when they were adopted the maintenance of schools was looked upon as a personal or local rather than a State concern. But later amendments introduced such provisions into all older State constitutions. And all newer ones contained strong and elaborate sections, making it a fundamental duty of the government they establish to encourage education and provide schools for all. All the States

have legislated much in reference to schools, and there is scarcely a session of one of the State legislatures in which they do not receive considerable attention. In all the States there is some sort of a State school organization established by law. In practically all there is an officer known as State superintendent of public instruction, or State school commissioner. In some there is a State Board of Education. In New York there is a State Board of Regents in charge of private academies, in some measure of public secondary schools, and of all higher institutions; and also a State Superintendent of Public Instruction, with authority over the elementary schools and in a large measure over the public high schools. The officer last referred to is probably vested with larger authority than any other one educational official in the country. He apportions the State school funds; determines the conditions of admission, the courses of work, and the employment of teachers; audits accounts of the 12 normal schools of the State; has unlimited authority over the examination and certification of teachers; regulates the official action of the school commissioners in all of the assembly districts of the State; appoints teachers' institutes, arranges the work, names the instructors, and pays the bills; determines the boundaries of school districts; and provides schools for the defective classes and for the seven Indian reservations yet remaining in the State. Besides he may condemn schoolhouses and require new ones to be built; and may direct new furnishings to be provided. He is a member of the State Board of Regents and of the board of trustees of Cornell University. He may entertain appeals by any person conceiving himself aggrieved from any order or proceeding of local school officials, determine the practice therein, and make final disposition of the matter in dispute, and his decision cannot be "called in question in any court or in any other place." All this, with the splendid organization of the State Board of Regents, provides New York with a more complete and elaborate educational organization than any other American State. Some think it more elaborate and authoritative than necessary. Certainly it is exceptional among the States, for most of them undertake to regulate school affairs very little, and usually the State Board of Education only controls the purely State educational institutions, and the principal functions of the leading educational official of the State are to inspire action, gather statistics, and disseminate information. However, there can be no doubt that the general tendency is toward greater centralization. The overwhelming current of legislation and of the decisions of the courts is making it imperative, being practically in accord, and to the effect that in each State the school system is not local, but general; not individual schools controlled by separate communities, but a closely related system of schools which has become a State system and is entirely under State authority; and holding local school officials as agents of the State for the administration of a State system of education. The granting of aid by the State implies the right of the State to name the conditions upon which the aid shall be received, and the duty to see that the exercise of such powers shall result in equal advantages to all. Despite of differences all the States ap-

EDUCATIONAL ORGANIZATION

preciate the fact that a constitutional self-governing state exists for the moral and intellectual advantage of every citizen. They have employed and will continue to employ different methods; but all have the highest authority and the supreme responsibility in the matter. And it is the purpose of the people and the law of most of the States not only that such educational opportunities shall be provided for every American child, but that every one shall be required to take advantage of them. Compulsory attendance laws have been enacted in most of the States. These are not as carefully framed as a good knowledge of educational administration might very easily lead them to be, and they are not as completely enforced as the true interests of many unfortunate children require. The right of compulsory education on the part of the State has met with considerable opposition and is still a much disputed question.

General Government and Education.—The Federal government has never exercised any control over the public educational work of the country. But it has never been indifferent thereto. It has shown its interest at different times by generous gifts to education and by the organization of a bureau of education to gather and disseminate the fullest information from all the States, and from foreign nations. The gifts of the United States to the several States to encourage schools have been in the form of land grants from the public domain. In the sale of public lands the practice of reserving one lot in every township "for the maintenance of public schools within the township" has uniformly been followed. In 1786 officers of the Revolutionary army petitioned Congress for the right to settle territory north and west of the Ohio River. A committee reported a bill in favor of granting the request, which provided that one section in each township should be reserved for common schools, one section for the support of religion, and four townships for the support of a university. This was modified so as to give one section for the support of religion, one for common schools, and two townships for the support of a "literary institution to be applied to the intended object by the legislature of the State." This provision, coupled with the splendid declaration that "religion, morality, and knowledge being necessary to good government and the happiness of mankind, schools and the means of education shall forever be encouraged," foreshadowed the general disposition and policy of the central government and made the "Ordinance of 1787 for the government of the Northwest Territory" famous. The precedent here established became national policy, and after the year 1800 each State admitted to the Union, with the exception of Maine, Texas, and West Virginia, received two or more townships of land for the founding of a university. In 1836 Congress passed an act distributing to the several States the surplus funds in the treasury. In all \$28,101,645 was so distributed, and in a number of the States this was devoted to educational uses. But the most noble, timely, and carefully guarded gift of the Federal government was embodied in the Land Grant Act of 1862 for colleges of agriculture and the mechanic arts, which gave to each State 30,000 acres of land for each senator and representative in Congress to which

the State was entitled under the census of 1860, for the purpose of founding "at least one college where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in such manner as the legislatures of the States shall respectively prescribe, in order to promote the liberal education of the industrial classes in the several pursuits and professions of life." This act has been added to by other congressional enactments and the proceeds of the sales of lands have been generously supplemented by the State legislatures until great peoples' colleges and universities have arisen in all of the States.

The work of the United States Bureau of Education is a most exact, stimulating, and beneficent one. Without exercising any authority, it is untiring and scientific in gathering data, in the philosophic treatment of educational subjects, and in furnishing the fullest information upon every conceivable phase of educational activity to whomsoever would accept it. It has become the great educational clearing-house of the world. Its commissioners have been eminent men and great educational leaders.

Private Institutions.—Besides public schools there is a large number of other schools which comprise an important part of the educational system of the country and are of course subject to its laws. Any statement concerning American school organization and administration, even of the most general character, would be incomplete which did not cover these. In the first half of the last century many private "academies" or "seminaries" sprang up where the country had become at all settled. This was in response to a demand from people who could not get what they wanted in the common schools. A teacher with a little more than ordinary gifts could open one of these private schools and soon have an abundance of pupils and a profitable income. But most of these schools served their purpose and gave way to new public high schools. Some remain and continue to meet the desires of certain families who prefer their somewhat exclusive ways. A considerable number have been adopted by their States and developed into State normal schools, and not a few have by their own natural force grown into literary colleges. In recent years innumerable schools have arisen out of private enterprise. Every conceivable interest, professional, technical, industrial, and commercial, has produced a school to promote its own ends.

All such schools operate independently of the States in which they exist. The States do not interfere with them, as they ask no public support. Some of them hold charters granted by the legislature, and more secure recognized standing by organizing under general corporation laws enacted to cover all such enterprises. In some cases the States distribute public moneys to some of these institutions by way of encouragement, and perhaps impose certain conditions upon which they shall be eligible to share in such distributions. But ordinarily a State does no more than protect its own good name against occasional impostors. New York, for example, has prohibited the use of the name "college" or "university" except when the requirements of the State Board of Regents are met. All reputable institutions

EDWARD THE ELDER — EDWARD

desire reasonable supervision, for it certifies their respectability and constitutes them a part of the public educational system of the State.

Expert Supervision.—From the beginning the laws have provided methods for certifying persons deemed to be qualified to teach in the schools. This has ordinarily been among the functions of State, city, and county superintendents or commissioners. Sometimes boards of examiners have been created whose only duty was to examine and certificate teachers. The function of certifying and that of employing teachers have, for obvious reasons, not commonly been lodged in the same officials. Superintendents began to be provided for by law in the early part of the 19th century. The first State superintendency was established by New York in 1812. Other States took similar action in the next 30 years. Town, city, and county superintendencies came along rapidly, and by or soon after the middle of the century had been set in operation in most parts of the then settled country. The main duty of these officials in the earlier days was to examine candidates for teaching, report statistics, and make addresses on educational occasions. In later years, however, they are held in considerable measure responsible for the quality of the teaching. In country districts superintendents hold institutes, visit schools, commend and criticise the teaching, and exert every effort to promote the efficiency of schools, so that a discreet and active county superintendent comes to exert almost a controlling influence over the school affairs of his county. In the cities, and particularly the larger ones, the problem is much more difficult. Because of the greater number of teachers, the task of securing uniform excellence is much enlarged. The schools are less homogeneous and instruction less easy. Frequently the superintendent cannot know the personal qualities of each teacher, or even visit all of the schools. Yet a system must be organized which, through the aid of assistants, will advise the superintendent's office fully of the work of every teacher. All teachers must be upon the merit basis, the most deserving must be advanced in rank and pay as rapidly as practicable, and the weak must be helped and trained into efficiency or removed from their positions. The laws are coming to recognize the responsibilities and difficulties of the superintendent's position, and are continually throwing about that officer additional safeguards and giving him larger powers and greater freedom of action. And the good cause of education against political manipulation is making substantial progress. The law books of all of the States show provisions recognizing the professional school superintendent; in many of the States they contain provisions directing and protecting his work: and in some they confer upon him entire authority over the appointment, assignment and removal of teachers, and impose upon him entire responsibility for the quality of the teaching. It is this professional supervision which has given the American schools their peculiar spirit. As the people have come to know the worth of good teaching they have favored closer supervision over the teaching. All this is yearly becoming more and more apparent in the laws, and it is advancing the great body of American teachers along philosophical lines more steadily and rapidly than

any other great body of teachers in the world is advancing.

In conclusion a few facts touching the great school system, the legal organization of which we have briefly tried to sketch, and which has produced that organization and in turn has in part been produced by it, will be of interest. The enrolment of pupils in the State common schools alone in 1899-1900 was nearly 15,350,000. These schools were kept open an average of 140.5 days in the year. The number of teachers employed was more than 420,000, and the running expenses for the year about \$213,000,000. Laws making attendance at school compulsory have been enacted in 32 States and Territories.

The United States Bureau of Education, to which I am indebted for the foregoing figures and much other information, is aided by a corps of 15,000 voluntary correspondents who furnish printed reports and catalogues and cheerfully answer the bureau's inquiries upon every phase of educational work.

It is of course difficult for one not familiar with American institutions and American ways to understand or appreciate the American school system. To him it seems anything but a system. It is a product of conditions in a new land, and it is adapted to those conditions. It is at once expressive of the American spirit and it is energizing, culturing and ennobling that spirit. It is settling down to an orderly and symmetrical institution, it is becoming scientific, and it is doing its work efficiently. It exerts a telling influence upon every person in the land, and is proving that it is supplying an education broad enough and of a kind to support free institutions.

ANDREW SLOAN DRAPER,
President University of Illinois.

Edward the Elder, king of England: b. about 870; d. Farndon, Northamptonshire, 925. He was a son of Alfred the Great, and succeeded his father in 901. Ethelwald, the son of his father's elder brother, claimed the crown; and an insurrection took place in his favor, but it ended with the death of Ethelwald in battle. The reign of Edward was further distinguished by successes over the Anglicized and foreign Danes. He fortified many inland towns, acquired dominion over Northumbria and East Anglia, and subdued several of the Welsh tribes.

Edward (surnamed the "MARTYR"), king of England: b. about 963; d. Corfe Castle 18 March 979. He was a son of Edgar, and succeeded his father in 975. His stepmother, Elfrida, wished to raise her own son, Ethelred, to the throne, but was opposed by Dunstan, through whose exertions Edward was peaceably crowned. His short reign was chiefly distinguished by the disputes between Dunstan and the foreign monks on one side, and the secular clergy on the other. Hunting one day in Dorsetshire he was separated from his attendants, and repaired to Corfe Castle, where Elfrida resided. He requested a glass of liquor, and as he was drinking on horseback one of Elfrida's servants gave him a deep stab behind. He immediately set spurs to his horse, but, fainting from loss of blood, was dragged in the stirrup until he died. The pity caused by his innocence and misfortune induced the people to regard him as a martyr.

EDWARD

Edward (surnamed the "CONFESSOR"), king of England: b. Islip, Oxfordshire, about 1004; d. 5 Jan. 1066. He was a younger son of Ethelred II. On the death of his maternal brother, Hardicanute the Dane, in 1041, he was called to the throne, and thus renewed the Saxon line. He was not the immediate heir, as his brother, Edmund Ironside, had left sons; but as he received the support of Godwin, earl of Kent, on condition of marrying his daughter, Editha, his claim was established. Edward was a mild and virtuous prince, who acquired the love of his subjects by his sanctity and care in the administration of justice. Having been educated in Normandy he introduced so many natives of that country to his court that the French language and manners became prevalent in England to the great disgust of Earl Godwin and his sons. A rebellion took place, and Edward was forced to dismiss his foreign favorites. Perceiving that the youth and weakness of his chosen heir, Edgar Atheling (q.v.), would not secure the succession against the power and ability of Harold, the son of Godwin, he turned his eyes upon his kinsman, William of Normandy, in whose favor it has been asserted that he executed a will. He died leaving the point of the succession undetermined; and with him ended the Saxon line of kings. He caused a body of laws to be compiled from those of Ethelbert, Ina, and Alfred, which is the supposed source of the common law of England. He was canonized by Alexander III. in 1166.

Edward I., king of England: b. Westminster 17 or 18 June 1239; d. Burgh-le-Sands, near Carlisle, England, 7 July, 1307. He was a son of Henry III., and the contests between his father and the barons called him early into active life, and he finally quelled all resistance to the royal authority by the decisive defeat of Leicester, at the battle of Evesham, in 1265. He then proceeded to Palestine, where he inspired so much terror that an assassin was employed to despatch him, from whom he received a wound in the arm, which, as tradition reports, being supposed to be from a poisoned weapon, was sucked by his faithful consort, Eleanor of Castile. On assuming the government he acted with great vigor in the repression of the lawlessness of the nobles and the corruption in the administration of justice; but often evinced an arbitrary and grasping disposition. In 1274, and again in 1276, he summoned Llewellyn, prince of Wales, to do him homage, and upon his refusal, except on certain conditions, began the war which ended in the annexation of that principality to the English crown in 1283. Edward then spent some time abroad in mediating a peace between the crowns of France and Aragon, and on his return commenced his attempts to destroy the independence of Scotland. After his return from the Scottish expedition in 1295, which terminated in the capture of Baliol, he became involved in a quarrel with his clergy, who, supported by the Pope, refused to submit to a tax which he had imposed on them. Edward forced their compliance by placing them out of the protection of the law. His frequent expedients to raise money at length produced great discontent among the nobles and people also, which obliged him to confirm the great charter and charter of forests, and also to give other securities in favor of public liberty. He

then made a campaign in Flanders against France, which terminated with the recovery of Guienne and his second marriage with Margaret, the sister of King Philip. Meantime new commotions took place in Scotland under the guidance of the celebrated William Wallace. These transactions recalled Edward from Flanders, who hastened to the border with an army of 100,000 men. The ignominious execution of the brave Wallace, in 1305, as a traitor, forms a blot in the character of Edward. Neither did it avail, since Robert Bruce was able, in 1306, to place himself at the head of a new confederacy. Indignant at this determined spirit of resistance Edward vowed revenge against the whole Scottish nation, and, assembling another army, was on the point of passing the border when he was arrested by sickness and death. Few princes have exhibited more vigor in action, or policy in council, than Edward I. His enterprises were directed to permanent advantages rather than to mere personal ambition and temporary splendor. Nor was he less intent upon the internal improvement of his kingdom than its external importance. The laws of the realm obtained so much additional order and precision during his reign that he has been called the "English Justinian." He passed an act of mortmain, protected and encouraged commerce; and in his reign first originated the society of merchant adventurers. The manners of this able sovereign were courteous, and his person majestic, although the disproportionate length of his legs gave him the popular surname of "Longshanks." He left a son and three daughters by his first wife, Eleanor, who died in 1290, and two sons by his second wife, Margaret of France. See Stubbs, 'The Early Plantagenets' (1877); Tout, 'Edward I.' (1893).

Edward II., king of England: b. Caernarvon Castle in 1284; d. Berkeley Castle 21 Sept. 1327. He was the first English Prince of Wales and succeeded his father, Edward I., in 1307. He was of an agreeable figure and mild disposition, but indolent and fond of pleasure. His first step was to recall Piers Gaveston, a young Gascon, whom his father had banished, and whom he created Earl of Cornwall, and married to his niece. He then went to France to espouse the Princess Isabella, to whom he had been contracted by his father, leaving Gaveston guardian of the realm. Soon after his return the barons associated against the favorite, whom they more than once obliged the king to send away. He was, however, as constantly recalled when the immediate danger was over, until an open rebellion took place; and the person of Gaveston being captured, he was executed as a public enemy. In 1314 Edward assembled an immense army to check the progress of Robert Bruce, but was completely defeated at Bannockburn. After the death of Gaveston he selected another favorite, Hugh le Despenser, upon whom he lavished favors of every kind, until the barons again rebelled, and the Parliament dooming Despenser and his father to exile, the king was obliged to confirm the sentence. Edward, however, on this occasion, in concert with the Despensers, contrived to raise troops and attack the barons, at the head of whom was his cousin, the Earl of Lancaster, who, being taken prisoner, was executed at Pomfret. Edward subsequently made another fruitless attempt against

EDWARD

Scotland, which ended in the conclusion of a truce of thirteen years. In 1324 Queen Isabella went to France, and while there entered into a correspondence with several English fugitives, in whose hatred to the Despensers she participated. Among these was Roger Mortimer, a young baron of the Welsh marches, between whom and Isabella a criminal intercourse followed, in consequence of which the queen was still more determined upon the ruin of her weak and unhappy husband. Having formed an association with all the English malcontents, and aided with a force by the Count of Hainault, she embarked for England in September, 1326, and landed in Suffolk. Her forces seized the Tower of London and other fortresses, captured and executed both the Despensers without trial, and at length took the king prisoner. Edward was confined in Kenilworth Castle, and in January 1327, his deposition was unanimously voted in Parliament, on the ground of incapacity and misgovernment. A resignation of the crown was soon after extorted from him, and he was transferred to Berkeley Castle, where Mortimer despatched two ruffians, who murdered him, in the 20th year of his reign and 43d of his age.

Edward II., an historical tragedy by Christopher Marlowe (1598). It follows history closely in its main lines and is a drama as powerful as it is painful.

Edward III., king of England: b. Windsor 13 Nov. 1312; d. Richmond, Surrey, 21 June 1377. He was a son of Edward II., and on his father's deposition in 1327, was proclaimed king under council of regency, while his mother's paramour, Mortimer, really possessed the principal power in the state. The pride and oppression of Mortimer now became so intolerable that a general confederacy was formed against him. The result was the seizure of Mortimer, who was tried and condemned by a parliament at Westminster, and was executed 29 Nov. 1330. The queen, although treated with outward respect, never again during the remaining 28 years of her life recovered any degree of authority. Edward now turned his attention to Scotland. Assisted by some principal English nobles, Edward Baliol, son of the John Baliol to whom the crown had been awarded by Edward I., raised a force, and defeating the Scots in a great battle, set aside David Bruce, then a minor, and was crowned at Scone in 1332. Baliol being driven away on the departure of his English auxiliaries, applied to Edward, who defeated the regent, Douglas, at the famous battle of Halidon Hill, in July 1333. This victory produced the restoration of Baliol, who was, however, again expelled, and again restored, until the ambition of Edward was called off by a still more splendid object. The crown of France, by the Salic law, having devolved to Philip de Valois, cousin-german to the deceased king Charles the Fair, Edward was induced to claim it in right of his mother, that monarch's sister. Edward, in order to obtain supplies, made concessions to Parliament which he never intended to keep; and finding his territory of Guienne threatened, sent over a force for its defense, and quickly followed himself, accompanied by his son Edward, the famous Black Prince, all his chief nobility, and 30,000 men. The memorable battle of Crécy

followed, 25 Aug. 1346, succeeded by the siege of Calais. In the meantime, David Bruce, having recovered the throne of Scotland, made an incursion, at the head of a large army, into England; but being met at Durham by a much inferior force, raised by Queen Philippa, and headed by Lord Percy, was totally defeated and taken prisoner, with many of his principal nobles. Philippa went over to her husband at Calais, and, by her interference prevented the barbarous execution of Eustache de St. Pierre and five other citizens, whom Edward, on the capitulation of the place, had determined to execute, in revenge for his long detention in the siege. In 1348 a truce was concluded with France. The year 1349 was distinguished by the institution of the order of the Garter, which soon became one of the most illustrious orders of knighthood in Europe. Philip, king of France, dying in 1350, was succeeded by his son John, the commencement of whose reign abounded with intestine commotion, and in 1355 Edward again invaded France on the side of Calais, while the Black Prince at the same time led a large army from Gascony. Both these expeditions were attended with much plunder and devastation; and Edward, being recalled home by a Scottish inroad, soon repelled it, and retaliated by carrying fire and sword from Berwick to Edinburgh. During this time the Prince of Wales had penetrated from Guienne to the heart of France, where he was opposed by King John, at the head of an army nearly five times more numerous than that of the English. The famous battle of Poitiers ensued, in which the French monarch being taken prisoner, Edward held at the same time in captivity the kings of France and Scotland, the most dangerous of his enemies. John was taken to England and treated with the greatest respect; and David was soon after liberated upon ransom. A truce had been made with France after the battle of Poitiers, at the expiration of which, in 1359, Edward once more passed over to Calais with a large army, but at length consented to a peace. Besides the stipulation of a large ransom for King John, several provinces and districts in the southwest of France and neighborhood of Calais were yielded to Edward, who in turn resigned his title to the crown of France and duchy of Normandy. The successor of John, Charles V., invaded the provinces entrusted to Prince Edward, then in the last stage of declining health, and Edward had the mortification of witnessing the gradual loss of all his French possessions, except Bordeaux and Bayonne, and of all his conquests except Calais. See Longman, 'Life and Times of Edward III.' (1869); Mackinnon, 'History of Edward III.' (1900).

Edward IV., king of England: b. Rouen, France, 29 April 1441; d. 9 April 1483. His father, Richard, Duke of York, was grandson of Edward, Earl of Cambridge, and Duke of York, fourth son of Edward III., while the Lancaster branch descended from John of Gaunt, the third son. The York line had intermarried with the female descendants of Lionel, the second son, which gave it the preferable right to the crown. Edward, on the defeat and death of his father at the battle of Wakefield, assumed his title, and having entered London after his victory over the Lancastrians at Mortimer's Cross, in Febru-

EDWARD

ary 1461 was declared king by acclamation. Soon after his accession he had to fight for his crown against an army of 60,000 Lancastrians, assembled in Yorkshire; and the field of Towton confirmed his title by a decisive victory. Although the high-spirited Margaret was enabled by the aid of Louis XI. of France again to take the field, the result of the battle of Hexham, in May 1464, obliged her to return to Flanders, and leave her husband, the imbecile Henry VI., a prisoner in the hands of his enemies. By a marriage with Elizabeth Woodville, widow of Sir John Grey of Groby, a Lancastrian, Edward plunged himself into very serious difficulties, since at the same time he had despatched the Earl of Warwick to negotiate a marriage for him with Bona, sister to the Queen of France; so that he at once offended two royal houses and his powerful friend Warwick. Aided by France, Warwick, who had contracted his daughter to the Lancastrian Prince Edward, landed with Clarence and some other lords at Dartmouth; and quickly saw himself at the head of 60,000 men, with whom he marched to encounter Edward. The king left Warwick in full possession of his kingdom, 11 days after he had set his foot in it. Henry's title was again recognized by Parliament, and Warwick and Clarence were declared regents of the kingdom. Edward subsequently landed at Ravenspur, in Yorkshire. Here his forces were reinforced by partisans from all quarters, and he was soon enabled to march to London, where he obtained entrance as king, and the unfortunate Henry again became prisoner. Warwick advanced against him as far as Barnet, where, on 4 April 1471, another great battle was fought, which ended in the death of Warwick, and a decisive victory on the part of Edward. On the same day Queen Margaret and her son landed at Weymouth, and marched into Gloucestershire, where she was met by the victorious Edward, who totally defeated her at Tewkesbury. The queen and her son Edward being taken prisoners and brought into the presence of the victor, Edward asked the latter how he dared to invade his dominions. On receiving a spirited answer he basely struck the captive prince on the face with his gauntlet — the signal for immediate massacre by the king's brothers and other nobles attendant. Margaret was thrown into the Tower, where Henry VI. soon after died, but whether by violence or by disease is uncertain. The latter part of his reign was disturbed by his jealousy of his brother Clarence, whom he put to death, it is said, by drowning in a butt of Malmsey wine.

Edward V., king of England: b. Westminster 2 or 3 Nov. 1470; d. London 1483. He was the eldest son of Edward IV., and was in his thirteenth year when he succeeded his father in 1483. He fell into the hands of his uncle, the Duke of Gloucester, the regent who caused the young king and his brother to be sent to the Tower, and, it is said, had them smothered by ruffians. Two bodies, answering their description, being found buried at the foot of the stairs of their apartment, in the reign of Charles II., were taken up by that king's order, and deposited in Westminster Abbey.

Edward VI., king of England: b. Hampton Court, England, 12 Oct. 1537; d. Greenwich 6 July 1553. He was the son of Henry VIII. by

Jane Seymour. At his father's death he was only 10 years of age, and as he did not live to attain majority, the public acts of his reign are to be deemed those of his counselors. His education was entrusted to men of the first character for learning, among whom was Sir John Cheke. He was studious, somewhat retiring, devout, and showed a decided preference for the reformed doctrines, and antipathy to those of the Roman Catholic Church. After his father's death his maternal uncle, the Duke of Somerset, became protector, but his administration raised up such powerful enemies that he was brought to the scaffold with the king's consent (1552). After his death Dudley, Duke of Northumberland, became all-powerful, and through his influence Edward, in a declining state of health, was induced to set aside the succession of both his sisters, and to settle the crown upon Lady Jane Grey, claiming through his father's youngest sister, the Duchess of Suffolk.

Edward VII., king of Great Britain and Ireland, and Emperor of India: b. Buckingham Palace 9 Nov. 1841, and baptized as Albert Edward. He is the eldest son and the second child of the late Queen Victoria and the prince consort, Prince Albert of Saxe-Coburg. On 14 December in the year of his birth he was, as heir-apparent, created Prince of Wales. After receiving a careful education under private tutors he studied at the universities of Edinburgh, Oxford, and Cambridge. In the summer of 1860 he visited Canada, where he was enthusiastically received, and by special invitation of President Buchanan extended his visit to the United States, where his reception was no less cordial. He was appointed a brevet-colonel in the army in 1858, and three years later was attached to the Curragh Camp in Ireland. In October 1861, he was made a bencher of the Middle Temple. In 1862 he was promoted to the rank of general, and in the spring of that year he set out on a visit to Egypt, Palestine, Syria, and Athens in company with the Rev. Arthur Penrhyn Stanley, afterward Dean of Westminster. After the Prince's return from the East he was introduced at the privy council, in 1863 he took his seat in the House of Lords, and about the same time formally gave up his right to succeed to the Duchy of Saxe-Coburg-Gotha. On March 10, 1863, at St. George's Chapel, Windsor Castle, he was married to the Princess Alexandra, eldest daughter of the King of Denmark. From this time onward the Prince discharged many important public ceremonial functions in various parts of the United Kingdom. Near the end of 1871 he was attacked by typhoid fever, and for a time it seemed as if his death were imminent, but he had completely recovered early in 1872. On 27 February of that year his recovery was made the occasion of a special thanksgiving service in St. Paul's Cathedral. In October 1875 he sailed from Dover on his journey to India. He arrived at Bombay in November, and between that date and his departure for England in March 1876 he visited the chief provinces, states, and cities of the Indian Empire, being everywhere received with the utmost cordiality and respect. With the Princess he made an extended tour through Ireland in 1885, and in 1888 his silver wedding was celebrated. The establishment of the Im-

EDWARD—EDWARDS

perial Institute as a memorial of the jubilee of the late queen (in 1887) was mainly due to his suggestion and exertions. In 1893 he sat on the Poor Law Commission, and in 1896 he was appointed chancellor of the newly created University of Wales. In the diamond jubilee year (1897) he established the Prince of Wales Hospital Fund for the better financial support of the London hospitals. At the great naval review of that year he represented Queen Victoria. By the death of his mother on 22 Jan. 1901, he became King of Great Britain and Ireland, and Emperor of India, and has elected to be known as Edward VII. On 14 February he and Queen Alexandra opened Parliament in state. To him and Queen Alexandra have been born: Albert Victor Christian Edward, Duke of Clarence and Avondale, b. 8 Jan. 1864, d. 14 Jan. 1892; George Frederick Ernest Albert, Duke of Cornwall and York, now heir-apparent, b. 3 June 1865, married 6 July 1893, to the Princess Victoria Mary of Teck; Princess Louise Victoria Alexandra Dagmar, b. 20 Feb. 1867, married 27 July 1889, to the Duke of Fife; Princess Victoria Alexandra Olga Mary, b. 6 July 1868; and Princess Maud Charlotte Mary Victoria, b. 26 Nov. 1869, married 22 July 1896, to Prince Charles, second son of the Crown Prince of Denmark.

Elaborate national and international preparations for the coronation ceremonies in Westminster Abbey were made for 26 June 1902; but on 24 June all festivities and ceremonies were suspended in consequence of a sudden illness requiring an immediate surgical operation. Owing to his fine natural constitution, the king fully recovered, and the coronation in a greatly modified form was accomplished 9 August. See 'The Private Life of King Edward VII.' (1901); 'Life of the King' by "One of His Majesty's Servants" (1901); 'From Cradle to Crown' (1902).

Edward, Prince of Wales, surnamed the Black Prince, English prince: b. Woodstock 15 June 1330; d. Westminster 8 June 1376. He was the eldest son of Edward III. and Philippa of Hainault, and at the age of 15 accompanied his father in his invasion of France, and received from him the honor of knighthood. The victory of Crécy, 26 Aug. 1346, which King Edward left principally to the exertions of the force under his son's command, to use that warlike king's language, "showed that he merited his spurs." It was on this occasion that he assumed the motto of *Ich dien* (I serve), used by all succeeding princes of Wales, and derived, it is said, from the crest of the King of Bohemia, slain in that battle, which tradition, however, later antiquaries seem disposed to discredit. In 1355 he commanded the army which invaded France from Gascony, and the next year fought the great battle of Poitiers, and distinguished himself by the courtesy with which he treated his prisoner, King John. By the Peace of Bretigny his father had obtained the provinces of Poitou, Saintonge, Périgord, Limousin, etc., which he annexed to Guienne and formed into a sovereignty for his son, under the title of the Principality of Aquitaine. There the prince took up his residence; and at his court Pedro the Cruel sought refuge, when driven from his throne by his natural brother, Henry of Trastamare. Edward undertook the re-establishment of this

tyrant, which he accomplished. Disappointed, by the perfidy of Pedro, of the stipulated reimbursements, the taxes he was obliged to levy on his new subjects rendered his government unpopular; and an appeal was made to the king of France, as his liege lord, who summoned him as his vassal to appear at Paris. "I will come," replied the angry prince, "but it shall be at the head of 60,000 men." His health, however, was too far declined to enable him to take the field, when the king of France invaded his dominions; and having suffered the mortification of seeing his generals defeated, he withdrew into England, and after lingering some time died in his 46th year, leaving an only son, afterward Richard II. He was buried in Canterbury Cathedral, where portions of his armor are still suspended above his tomb.

Edward, Thomas, Scottish naturalist: b. Gosport 1814; d. 27 April 1886. As the apprentice of a shoemaker he spent the early part of his life in Aberdeen, and in 1837 married and settled in Banff. Here he struggled for 40 years in a ceaseless effort to acquire a close knowledge of natural history, while at the same time he supported his wife and 11 children on wages that never exceeded 15 shillings a week. Apart from his laborious work as a shoemaker he collected, described, and exhibited numerous specimens of natural history. A biography of Edward, written by Samuel Smiles (q.v.) appeared in 1876, 'Life of a Scotch Naturalist,' and being thus prominently brought before the public, a pension of £50 a year was conferred upon him by the Queen.

Edwards, Amelia Blandford, English Egyptologist and novelist: b. London 1831; d. Weston-super-Mare, Somerset, 15 April 1892. Her novels include: 'My Brother's Wife' (1855); 'Hand and Glove' (1859); 'Half a Million of Money' (1865); 'Lord Brackenbury' (1880); 'Barbara's History,' and 'In the Days of My Youth' (1873). Later she achieved great celebrity through her writings and lectures in Europe and the United States on the antiquities of Egypt; her best-known works in this field are: 'A Thousand Miles Up the Nile' (1877); and 'Pharaohs, Fellahs, and Explorers' (1891). She also translated Maspero's work on 'Egyptian Archaeology,' and was secretary of the Egyptian Exploration Fund.

Edwards, Bela Bates, American Congregational clergyman: b. Southampton, Mass., 4 July 1802; d. Athens, Ga., 20 April 1852. He was graduated at Amherst College in 1824, was appointed tutor there in 1826, and was assistant secretary of the American Education Society, 1828-33. He edited the 'American Quarterly Register,' 1828-42; founded the 'American Quarterly Observer' in 1833, and edited it after consolidation with the 'Biblical Repository' in 1835-8; edited the 'Bibliotheca Sacra' (1844-52). In 1837 he became professor of Hebrew at Andover Theological Seminary, and in 1848 professor of biblical literature there, which posts he held till his death.

Edwards, Mrs. Bennett, English novelist. She has published 'A Tantalus Cup'; 'In Sheep's Clothing'; 'Pharisees'; 'The Unwritten Law'; 'Saint Monica'; 'His Story and Hers'; 'A Woman in Spectacles.'

EDWARD VII
KING OF ENGLAND

Edwards, Bryan, English historian of the West Indies: b. Westbury, Wiltshire, 21 May 1743; d. Southampton 15 July 1800. On the death of his father he was taken under the care of an uncle in Jamaica, who left him a large fortune. After a successful mercantile career he returned to England, and in 1796 took his seat for the borough of Grampound, which he represented until his death. He is remembered for his 'History, Civil and Commercial, of the British Colonies in the West Indies' (1793). A new edition of this work (1801) includes a history of San Domingo. He also published 'Proceedings of the Governor and Assembly of Jamaica in regard to the Maroon Negroes' (1796).

Edwards, Edward, English librarian: b. London 1812; d. Niton, Isle of Wight, 10 Feb. 1886. He published 'Memoirs of Libraries' (1859); 'Lives of the Founders of the British Museum' (1870); 'Sir Walter Raleigh' (1885).

Edwards, George, English sociologist: b. 1752; d. London 17 Feb. 1823. Possessed of the conviction that he held the precious secret of the relief of man's estate, he wrote some 50 books to disseminate the information, among which is one with the long title: 'The Practical System of Human Economy, or the New Era at Length Fully Ascertained, Whereby We are Able in One Immediate Simple Undertaking to Remove the Distress, Burdens, and Grievances of the Times, and to Bring All our Interests, Public, Private, and Commercial, to their Intended Perfection' (1816).

Edwards, George Wharton, American artist and author: b. Fair Haven, Conn., 1859. His works include: 'P'tit Matin and Other Monotones' (1887); 'Thumb-Nail Sketches' (1886); 'The Rivalries of Long and Short Codiac' (1888); 'Break o' Day, and Other Stories' (1889). He is at present art director of 'Collier's Weekly.'

Edwards, Harry Stillwell, American journalist and novelist: b. Macon, Ga., 23 April 1854. He was graduated from the law department of Mercer University, and practised law, but in 1871 entered journalism in his native city. He is well-known as a writer of dialect stories. Among his works are: 'Two Runaways, and Other Stories' (1889); 'Sons and Fathers'; 'The Marbeau Cousins'; 'His Defense, and Other Stories.'

Edwards, Henri Milne-. See MILNE-EDWARDS.

Edwards, Henry Sutherland, English author: b. London 1828. He traveled and studied in Russia, Turkey, and central Europe, acting as newspaper correspondent. He has written 'The Polish Captivity' (1863); 'Life of Rossini' (1869); 'The Germans in France' (1874); 'The Slavonian Provinces of Turkey' (1876); 'The Prima Donna: Her History and Surroundings from the 17th to the 19th Century' (1888); 'Dutiful Daughters' (1890), a tale of London life; 'Personal Recollections' (1900).

Edwards, John, American poet: b. near the river Twrch, Wales (whence known as Eos-Glan-Twrch, or "the nightingale of the Twrch"), 15 April 1806; d. near Rome, N. Y., 20 Jan. 1887. He did much to promote the publication in America of Welsh periodicals. His published

poems include 'The Crucifixion' (1853), and 'The Omnipresence of God' (1859).

Edwards, Jonathan, American metaphysician, and theologian: b. East Windsor, Conn., 5 Oct. 1703; d. Princeton, N. J., 22 March 1758. His father, a minister of the gospel, instructed him in the dead languages. The son entered Yale College, New Haven, in 1716, and after taking his degree in 1720, remained nearly two years at Yale, preparing for the Congregational ministry. In September 1723 he was elected a tutor in Yale College, and in the following year began to act in that capacity, but resigned in 1726, in order to become minister at Northampton, Mass., where he was ordained 15 Feb. 1727. His various sermons and disquisitions procured for him a wide reputation. His 'Treatise on Religious Affections' was immediately republished in England and Scotland, and placed him among the first writers of his sect. After more than 23 years of zealous service in Northampton, a rupture occurred between him and his congregation owing to the candor with which he publicly reprovved certain irregularities of some young persons connected with families in his church. An ecclesiastical council dismissed him in June, 1750; and in the following year he accepted a call to serve as a missionary among the Indians at Stockbridge, Mass. Here he remained six years, exerting himself with an apostolical spirit, and at the same time prosecuting the deepest investigations in mental philosophy. Here he composed his famous works on the 'Freedom of the Will,' and on 'Original Sin.' The first is his masterpiece, and worthy of the powers of a Locke, or Leibnitz. It was completed within the space of four months and a half. The date of its first appearance is the early part of 1754. In 1757 he was chosen president of the college at Princeton, N. J., and accepted this invitation, though not without reluctance, on account chiefly of his desire to accomplish two great literary enterprises which he had begun long before—a 'History of the Work of Redemption,' and a 'View of the Harmony of the Old and New Testaments.' In January 1758 he went to Princeton, where he died two months later. See 'Life' by Dwight (1830); Allen, 'Jonathan Edwards' (1889).

Edwards, Jonathan (the younger), American theologian: b. Northampton, Mass., 26 May 1745; d. Schenectady, N. Y., 1 Aug. 1801. At the age of six years he went with the family of his parents to Stockbridge, where there was but one school, and that common to the children of both the Indians and white inhabitants, of the latter of whom there were so few that he was in danger of forgetting the English tongue. He so thoroughly learned the language of the Stockbridge Indians, that, as he tells us, all his thoughts ran in their dialect. This knowledge of their language he retained through life. In 1761 he entered the college at Princeton, N. J., where he was graduated in 1765. After leaving college he studied divinity, and in 1776 was licensed as a preacher of the gospel. In 1769 he was ordained as pastor of the church in White Haven, in the town of New Haven, Conn., where he continued till May 1795. Resigning this charge, mainly on account of difference in doctrinal views between himself and some of his

EDWARDS—EDWY

people, he was settled in 1796 as pastor of the church in Colebrook 1796-9, where, in addition to professional duties, his time was devoted to his favorite studies, and to an extensive correspondence which he had long carried on with learned men both in this country and in Europe. In May 1799 he became president of Union College, Schenectady, which office he filled at the time of his death. He was the author of a treatise on 'Liberty and Necessity' (1797); and 'Discourses on the Atonement' (1785). See life by Tryon Edwards.

Edwards, Julian, American composer: b. Manchester, England, 17 Dec. 1855. His opera, 'Victorian,' its libretto adapted from Longfellow's 'Spanish Student,' was produced in London in 1884. Since coming to New York in 1888 he has composed the operas: 'Jupiter' (1892); 'Friend Fritz' (1893); 'King René's Daughter' (1893); 'Madeline' (1894); 'Brian Boru' (1896); 'The Wedding Day' (1897), and various other music.

Edwards, Justin, D.D., American Congregational clergyman: b. Westhampton, Mass., 25 April 1787; d. Virginia Springs 23 July 1853. He was graduated at Williams College in 1810, settled in the ministry at Andover in 1812, removed thence to the Salem Street Church, Boston, in 1828, and in 1829 resigned this charge to become secretary of the American Temperance Society, in the service of which he was engaged for seven years, presenting its cause with great ability and success, by lectures and addresses. After this, he was for six years president of the Andover Theological Seminary. He was the author of several tracts on moral and religious subjects, some of which had a wide circulation. Of his 'Temperance Manual,' some 200,000, and of the different parts of his 'Sabbath Manual,' nearly 2,000,000 copies have been published.

Edwards, Matilda Barbara Betham-. See BETHAM-EDWARDS, MATILDA.

Edwards, Oliver, American soldier: b. Springfield, Mass., 30 Jan. 1835. He entered the Union army at the beginning of the Civil War, and rose, gaining almost every step by acts of personal gallantry, to the rank of brigadier-general in 1865. After the War he engaged in mercantile pursuits.

Edwards, Osman, English lecturer and dramatic critic: b. Liverpool 18 Feb. 1864. He has published 'Short Studies of Theatrical Life' from the French of Daudet (1892); 'A Gauntlet' from the Norwegian of Björnson (1894); 'Residential Rhymes' (1899); 'Japanese Plays and Playfellows' (1901).

Edwards, Pierrepont, American lawyer, son of Jonathan Edwards (q.v.): b. 1750; d. 1826. He was graduated at Princeton in 1768, and admitted to the bar in 1771. He served in the Revolutionary Army, became a member of the Continental Congress and subsequently was appointed a district judge in Connecticut. As founder of the Toleration Party he was very unpopular in New Haven.

Edwards, Richard, English dramatist: b. Somersetshire 1523; d. 31 Oct. 1566. He was educated at Oxford, where he obtained distinction for scholarship, and became under Elizabeth one of the gentlemen of the queen's chapel,

and had charge with others of the theatrical representations before the children there. His 'Damon and Pythias' was the first English tragedy on a classical subject, and was acted before the queen at Oxford in 1566. Though esteemed among the best writers of interludes and rude comedies of the time, all his other dramas are lost. He wrote several minor poems, one of which, entitled 'Amantium Ira,' has been often reprinted in modern collections.

Edwards, William, American inventor: b. Elizabeth, N. J., 11 Nov. 1770; d. Brooklyn, N. Y., 1 Dec. 1851. After receiving a common school education he learned the tanning trade, and built his own tannery at Northampton, Mass., but eventually settled in Hunter, Greene County, N. Y. Here he opened a model tannery, with improvements in manufacturing appliances originated by himself. His principal invention was a leather-rolling machine, which saved the labor of hammering. He invented other machines, and utilized water power to such an extent as practically to revolutionize the tanning business in the United States, improve the quality of shoe-leather and cheapen its cost.

Edwards, William Henry, American naturalist: b. Hunter, Greene County, N. Y., 15 March 1822. He was graduated at Williams College 1842, and was admitted to the bar 1847. In 1846 he traveled in South America, going up the Amazon River and making a natural history collection. He has published: 'Voyage up the Amazon' (1847); 'The Butterflies of North America' (1879, 1884 and 1897); 'Shaksper, not Shakespeare' (1900); and contributed over 150 papers on Lepidoptera to the 'Canadian Entomologist.'

Edwardsville, Ill., city, county-seat of Madison County; on the Illinois Terminal, the T. St. L. & K. C., and the Wabash R.R.'s, about 70 miles southwest of Springfield, and 20 miles northeast of St. Louis, Mo. It is the centre of a coal mining and agricultural region. The industries are such as are adapted to the country, including several plants for the manufacture of tools and other hardware. Pop. 4,212.

Edwin, king of Northumbria: b. about 585; d. 633. He was the son of Ella, who seems to have ruled that kingdom from 559 to 589. Being an infant at his father's death the crown was seized by Ethelfrith of Bernicia. The young prince was sent for protection to the court of Redwald, king of East Anglia, by whose aid he was eventually put upon the throne (617). He married Ethelburga, daughter of Ethelbert of Kent, and by her influence and that of Paulinus, a Roman missionary, whom she had brought from her father's court, was led to embrace Christianity, and make it the religion of his people. He was baptized in 627 at York, where he built the first church of wood. The Mercians, under Penda, revolted against the supremacy claimed by the Northumbrians; and the war which ensued was closed by a battle at Heathfield, or Hatfield, in Yorkshire, in which Edwin was defeated and slain.

Edwin Drood. See MYSTERY OF EDWIN DROOD.

Edwy, king of England: b. about 938; d. 958. He was son of Edmund I., and succeeded his uncle Edred in 955. Taking part with the

secular clergy against the monks, he incurred the confirmed enmity of the latter. Having called Dunstan to account for his share in the administration in the preceding reign, the latter refused to attend the summons, and was in consequence banished. His party was, however, so strong that a rebellion was excited, and Edwy driven from the throne, to make way for his brother Edgar.

Beckhout, ěk'howt, or **Eckhout**, **Gerbrand van den**, Dutch painter: b. Amsterdam 19 Aug 1621; d. there 22 July 1674. He was one of the pupils of Rembrandt, and in some measure successful in imitating his manner, especially in the early part of his life. He excelled chiefly in painting portraits, and these as well as his historical pictures abound in the best collections of Holland, while several of them are to be found in Germany. His most esteemed work represents Christ among the doctors.

Eecloo, ā-klō', Belgium, town in province of East Flanders, 11 miles northwest from Ghent, near the Liève. The manufactures are chiefly woolens, cottons, hats, tobacco, chocolate, soap, and starch; and it has breweries, distilleries, salt-refineries, dye-works, and oil-mills; and an active trade in grain, linen, cattle, and timber. Pop. 13,200.

Eekhoud, ěk'howt, **Georges**, Belgian novelist and poet: b. Antwerp 27 May 1854. He first published two volumes of poetry, 'Myrtles and Cyresses' (1876); and 'Poetic Zig-Zags' (1877); then became a newspaper literary critic in Brussels, and wrote several short stories. His first considerable novel, 'The Militia of St. Francis' (1886), is a masterly portrayal of Flemish peasant life, especially its naïve mystic religiousness. His masterpiece, 'New Carthage' (1888), paints Antwerp life in its naked actuality. Still other works of his are: 'The Fusillades at Mechlin' (1890), a story of the peasants' uprising against the French in 1798; and 'La fanéuse d'amour' (1900). In poetry he has developed from romanticism to pronounced realism.

Eel, the general name given to a variety of teleostomous fishes of diverse structure and resembling one another chiefly in their elongated form, soft rayed fins, and the tendency for the paired fins to become reduced in size. Although their seclusive habits render the eel-like fishes liable to be overlooked, and it is evident that many remain undiscovered, the number and diversity of those already known are very considerable. Ichthyologists have arranged them in numerous families and several orders, which Prof. Cope regarded as forming a series degenerate in respect to the gradual loss of the paired fins, and certain ossifications of the skull, and in the simplification of the gill arches. According to the classification of Jordan and Evermann, most of the eels fall within the order Apodes, the others chiefly within the *Plectospondyli*, *Symbranchia*, and *Carenchelyi*. The common eel or fresh-water eel (*Anguilla chrysa*, but also described under a number of other names) belongs to the first order and the family Anguillidae. It is doubtfully distinct from the European fresh-water eel (*Anguilla anguilla*). Both species are characterized—in addition to the serpent-like elongated body, the absence of ventral fins, and the continuity of the dorsal and anal fins round the

extremity of the tail—by the wide interval between the dorsal fin and the head, the projecting lower jaw, well developed pectoral fins, well ossified jaws and gill covers and nearly perfect gill arches. Contrary to the common belief eels are not scaleless but numerous small scales are embedded in the skin. The life history of the eel is very remarkable and in some respects unique. During the spring and early summer multitudes of young eels several inches long migrate up the rivers from the sea and distribute themselves throughout every accessible body of water, whatever its size or character, frequently traveling overland to reach these. Here they remain concealed in the mud or beneath stones and feed on all kinds of animal matter, living and dead, in the pursuit of which they are relentless. Many eels appear never to leave the fresh waters in which they have developed, but most of them after several years return to the sea and enter comparatively deep waters, where sexual maturity and spawning takes place. From the egg a peculiar, compressed, transparent, pelagic larva (*Leptocephalus brevirostris*) is produced, which in due time generally metamorphoses into the young eel which in turn leaves the sea. Some individuals, however, appear to remain permanently in salt as others do in fresh water.

Both in America and in Europe eels are an important and very excellent food fish, and great quantities are caught in a variety of ways. In the United States use is made of hand and set lines, eel spears, eel pots, and weirs. The last is the most efficacious method, but owing to its serious destructiveness of shad and other fishes its use is frequently prohibited by law. A V-shaped fence or net is arranged across the stream with a basket placed in a small opening at the apex, into which the eels are guided by the leads and from which they are unable to extricate themselves. In England river eels are caught in great numbers by means of eelbucks, or eel-pots, traps consisting of a kind of basket with a funnel-shaped entrance composed of willow rods converging toward a point, so that the eels can easily force their way in but cannot return. A stocking or tube of coarse cloth hanging from an aperture of a box down into the interior is also used. A kind of trident, called an eel-spear, is used also for taking them. A fisherman wades to the shallows, and, striking his spear in the mud in every direction around him, the eels reposing on the bottom are caught between the prongs. Except a few other species of the same genus as the common eel all eels are strictly marine and are especially numerous in tropical seas where, in the interstices of coral reefs, as also in the deep sea, some very remarkable kinds occur. For an account of the species consult Jordan and Davis, Report U. S. Fish Commission for 1888; Jordan and Evermann, Bulletin U. S. National Museum, No. 47, Pt. I.; and Goode and Bean, 'Oceanic Ichthyology.' See also articles: CONGER EEL; ELECTRIC EEL; SNIPE EEL; MORAY; PELICAN FISH; SNAKE EEL, etc.

Eel-grass, or **Grass-wrack**, a common name for a marine grass, *Zostera marina*, of the pondweed family (*Naiadaceae*). The leaves are narrow and ribbon-like, blunt at the end, sometimes six feet in length. The flowers are crowded in a spadix. It is found in bays or

streams along the Atlantic coast from Greenland to Florida, and on the Pacific from Alaska to California, also on the shores of Europe and Asia. The genus *Zostera* (from the Greek, referring to the ribbon-like leaves), comprises six genera, of which two besides the eel-grass are found in America. They are all marine plants, and are found on the coasts in the north temperate zone.

Eel-pout, the name of various fishes. It is applied in the United States to the burbot or ling of the Great Lakes and to the mutton-fish; in Great Britain to the burbot (q.v.), and in northern Africa to the electric catfish (*Malapterurus*).

Eells, Myron, American Congregational clergyman: b. Walker's Prairie, Wash., 7 Oct. 1843. He was graduated at Pacific University, Ore., 1866, and at Hartford Theological Seminary 1871. He was pastor at Boise City, Idaho, 1872-74, later serving as missionary to the Indians at Skohomish, Wash., where he filled the pulpit of the Congregational Church 1876. Among his works are: 'History of Congregational Association of Washington and Oregon' (1881); 'History of the Indian Missions on the Pacific Coast' (1882); 'Ten years at Skohomish' (1886); 'Father Eells' (1894).

Eelworm, or Vinegar Eel (*Anguillula aceti*), a small *Nematoda* (q.v.) worm of the family *Anguillulidae*, often found in immense numbers in good cider vinegar or in sour paste, where it feeds on the mucilage and organic fluids. It is just visible to the naked eye and wriggles very actively. Like many related species it is very resistant to dessication and other influences ordinarily destructive to animal life. A vast number of similar species live in the earth and feed on decaying organic matter, others are parasitic on plants, in which they are at least the partial causes of certain very serious diseases; thus *Tylenchus devastatrix* causes the "clover disease" and *Heterodera schachtii* the still more destructive "beet sickness," which sometimes devastates the sugar beet crop of Germany.

Effendi, a title of respect among the Turks, bestowed on civil officials, and on educated persons generally, in contradistinction to the military title of *aga*. It is nearly equivalent to the French *Monsieur*, but is suffixed to the personal name.

Effigy, formerly **Effigie**, (1) a copy or imitation of an object, an image or likeness; in sculpture frequently applied to the figures on sepulchral monuments; (2) to execute or degrade, as the execution or degradation of a condemned criminal, when he cannot be personally apprehended, by subjecting his image to the formalities of an execution; for instance, affixing the image with a rope round the neck to the gallows (hanging in effigy). This practice is not altogether extinct in Prussia, and in other countries; but in England it has become merely a mode in which the populace expresses its feelings respecting an obnoxious personage; such as the English custom of parading and burning the effigy of Guy Fawkes on 5 Nov.

Effingham, Ill., city, county-seat of Effingham County; on a branch of the Wabash River, about 240 miles south by west of Chicago, and on the Illinois C., the Wabash, and Vandalia

R.R.'s. The city is the trading point of an agricultural region, and has some small manufacturing. It contains Austin College and a large photographic school. Pop. 3,825.

Efflorescence, a term applied to crystals, which, on exposure to the air, lose water of crystallization and crumble down into a powder. The most familiar instance is that presented by the glassy crystals of washing soda, which become white and pulverulent in the air. The same phenomenon is also presented by phosphate of sodium, borax, and other compounds. Another application of the word is to the fine white, feathery crystallization of sulphate and carbonate of sodium which appears on walls, or similar crystallizations on the surface of the earth, in decomposing rocks, etc. Efflorescence is in some respects the opposite of deliquescence, and the difference is shown by placing an efflorescent and deliquescent body under a bell-jar. The former gives up its water, which the latter absorbs, becoming thereby fluid. See **CRYSTALS**.

Effusion (Lat. "to pour out"), in physics and chemistry, the escape of a gas into a vacuum, through a small opening (such as a pin-hole) in a thin partition. So long as the temperature of the gas is constant, the velocity of effusion is independent of the pressure. For the same gas at two different temperatures (but at the same density), the velocity of effusion varies directly as the square root of the absolute temperature. The velocities of effusion of two different gases (both at the same constant temperature) are inversely proportional to the square roots of the densities of the gases; the densities being determined by comparison under convenient but identical conditions of temperature and pressure.

Eft, a name given to several species of newts, especially to the common smooth newt (*Lissotriton punctatus*). The eft has a slightly free tongue, double longitudinal series of palatal teeth, and nailless toes, four before and five behind. The skin is smooth; the dorsal and caudal crests are continuous; there are two patches of glandular pores on the head, and none on the back or sides. The color in the male is brownish gray above, passing into yellowish beneath, which in the spring becomes bright orange; there are numerous round dark spots of unequal size, and two longitudinal streaks on the head; the crest in spring is often tipped with red or violet. The female is light yellowish brown, or buff with brown dots, plainer below. The total length is about 3½ inches, of which the tail is nearly one half. It is very common in the ditches and ponds of Europe, especially where the water is clear. Its food consists principally of aquatic insects, larvæ, worms, and mollusks. The reproduction and metamorphosis are almost identical with those of the newts. Though usually spending most of their time in the water, the young in June, and the adults in summer and autumn, become terrestrial; they appear to attain their full size the first year. Their bite is perfectly harmless. They are eaten by the larger amphibians, by fishes, and by various reptiles, birds, and small mammals.

E'gan, Maurice Francis, American author: b. Philadelphia 24 May 1852. He was graduated at La Salle College; and was subsequently

professor of English literature in the University of Notre Dame, Ind., and professor of English language and literature in the Catholic University of America in Washington, D. C. His publications include: 'That Girl of Mine' (1879); 'Preludes' (1880), a book of poems; 'Songs and Sonnets' (1885); 'The Theater and Christian Parents' (1885); 'Stories of Duty' (1885); 'A Garden of Roses' (1886); 'The Life Around Us' (1886); 'Studies in Literature'; 'The Watson Girls'; etc.

Egan, Patrick, American politician: b. County Longford, Ireland, 1841. He became identified with the Nationalists and the Home Rule Movement in 1871, and was one of the organizers of the Irish Land League. He was tried in Dublin in 1880 for conspiracy and sedition, going to Paris upon his acquittal. He came to the United States in 1883, and was president of the Irish National Land League of America 1884-86. He testified before the Parliamentary Commission 1889, and was instrumental in securing the failure of the case of the London *Times* against Parnell. He was appointed minister plenipotentiary to Chile as a reward for his speeches in the campaign of 1888. In Chile he espoused the cause of Balmaceda, the Liberal Dictator. Later he left the Republican party, becoming what was termed a Free Silver Democrat, and taking part in the subsequent campaigns in favor of that issue.

Egan, Pierce (the Elder), English sporting writer: b. London 1772; d. there 3 Aug. 1849. A prolific "historian of the ring" and kindred institutions, he wrote 'Boxiana' (1818); and the widely popular 'Life in London' (1821); which was illustrated by Cruikshank.

Egan, Pierce (the Younger), English novelist: b. London 1814; d. there 6 July 1880. He was a son of the preceding. At first an artist, he turned to fiction, winning fame with 'Robin Hood' (1840); 'Wat Tyler' (1841), and similarly conceived romances; while his later and more sensational tales, 'Imogen'; 'Fair Lillias'; and others, appeared for the most part as serials only.

Egaña, Juan, hoo-än' ā-gā'ña, Chilean author and statesman: b. Lima 1769; d. Santiago, Chile, 13 April 1836. He took an active part in the revolution, was a member of the first Chilean Congress, was captured and imprisoned on Juan Fernandez Island, but was liberated in 1817, and was again a member of Congress until elected president of the Republic in 1823. He was a voluminous writer, both of poetry and prose, his works including several educational text-books. He exercised great influence in shaping the character of the people and the policy of Chile.

Egbert, king of Wessex: b. about 775; d. 837. On the death of Alcmund, the former king, Brihtric, a powerful noble, succeeded in ousting Egbert, who had the best claim to the throne, and was compelled to take refuge first in the court of Offa of Mercia, then in that of Charlemagne. On the death of Brihtric he succeeded him as king of Wessex, in 800. He reduced the other kingdoms, and rendered them dependent on him, in 827, and is thus considered the first king of all England.

Egbert, Harry C., American military officer: b. Pennsylvania 3 Jan. 1839; d. 4 March 1899. He entered the army as first lieutenant in September 1861; was promoted captain in 1865; major in 1890; and colonel on 1 July 1898. In October of the latter year he was commissioner brigadier-general of volunteers. When the war with Spain broke out he commanded the 6th Infantry, of which he was lieutenant-colonel. In the Santiago campaign, while leading a charge at El Caney, 1 July 1898, he was shot through the body. He had scarcely recovered from his wound when he applied for service in the Philippines. He arrived at Manila with his regiment 4 March 1899, and was killed while storming Malinta, on the 26th.

Egbert, James Chidester, Roman archæologist and epigraphist: b. New York 1859. He was graduated at Columbia University in 1881, and held a prize fellowship (1882-85). He began to teach in the University in 1885 and was adjunct professor of Latin 1885-90. In 1890 he was appointed professor of Roman archæology and epigraphy in Columbia, and while he has done much to promote the study of these special subjects, and has published: 'Introduction to the Study of Latin Inscriptions,' he has also edited 'Cicero de Senectute'; and written 'Macmillan's Shorter Latin Course.'

Egede, Hans, hänts ā'gē-dē, Danish missionary, termed the apostle of Greenland: b. Harstad, Norway, 1686; d. Falster, Denmark, 1758. In 1707 he became a preacher at Wogen. Having heard that Christianity had been once established in Greenland, but had become extinct in the country for want of teachers, he resolved to visit the country, and to preach the gospel to the inhabitants. Having received from the Danish government the title of royal missionary to Greenland, with a small pension and three ships, he sailed on 21 May 1721 with 46 persons under his command. Egede landed on 4 June, and the conversion of the Greenlanders was now undertaken, but offered great difficulties. Egede took up his residence, with his two sons, among the natives, in order to learn their language, and so be able to carry out his project of conversion. He carefully noted down every word of which he discovered the meaning; often performed long journeys, at the peril of his life, to visit the remotest Greenlanders, for the purpose of gaining their confidence, in which he succeeded by a thousand acts of kindness. After spending fifteen years in Greenland, amid innumerable discouragements, he returned in 1736 to Copenhagen, to make new exertions for the support of Christianity in that country. The government appointed him director of the Greenland missions, and established his son Paul in the office of missionary there. His writings are in Danish, and relate to the natural history of Greenland, and his sufferings and adventures there.

Egede, Paul, Danish missionary: b. 1708; d. Copenhagen 1789. He was a son of Hans Egede and was his assistant from the time he was 12 years old. Notwithstanding a strong inclination for the naval service, he submitted to the wishes of his father, studied divinity, joined the mission in Greenland in 1734, and remained there till 1740. He then returned to Copenhagen, and afterwards was appointed

Bishop of Greenland. We have from him an 'Account of Greenland,' extracted from a journal kept from 1721-88; 'Dictionarium Grœnlandicum'; 'Grammatica Grœnlandica'; and translation of the Gospels, the 'Imitation of Christ,' etc., in the Greenland tongue.

Egelhaaf, ä'gël-häf, **Gottlob**, German historian: b. Gerabronn, Württemberg, 1 March 1848. He has published: 'A History of Germany During the Reformation' (3d ed. 1893); 'Emperor William' (3d ed. 1888); 'A History of Germany During the Sixteenth Century until the Peace of Augsburg' (1888-92); and other works.

Eger, ä'gër, Bohemia, town in the northwest, on a rocky eminence above the Eger, 91 miles west of Prague. It was once an important fortress, founded in the 12th century. Six lines of railroads converge at Eger. There are various industries, including machinery, wool, cotton, and leather manufactures, and a flourishing trade. The celebrated Wallenstein was assassinated here (1634). Franzensbad, a watering place, is connected with Eger by an avenue three miles long. Pop., of the commune, 24,200.

Eger, a river which rises in Bavaria, in the Fichtelgebirge, 12 miles northwest of the town of Eger, flows first southeast, then takes a northeasterly direction into the Elbe, near Leitmeritz, in Bohemia, after a course of about 190 miles.

Egeria, ê-jë'rî-ä, (1) a nymph who received divine honors among the Romans. Numa is said to have had secret conversations with her, and to have received from her the laws which he gave to the Romans. Some say Egeria was the wife of Numa. (2) a genus of spider crabs of the family *Maidæ*; (3) a genus of bivalve shells of the family *Donacidae*; (4) in astronomy, the thirteenth planetoid, discovered by De Gasparis, at Naples (1850).

Egerton, ëj'ër-tôn, **George** (pseudonym of MRS. MARY CHAVELITA DUNNE MELVILLE CLAIRMONTE BRIGHT), English novelist: b. Australia 14 Dec. 1860. She was married in 1888 to H. Melville, who died in 1889; in 1891 to Egerton Clairmonte, who died in 1901; and in 1901 to R. G. Bright. She has traveled extensively, visiting the United States four times. She has published: 'Key-notes' (1893); 'Discords' (1894); 'Young Ofeg's Ditties' (1895); 'Symphonies' (1897); 'Fantasias' (1898); 'The Wheel of God' (1898); 'Rosa Amorosa' (1901); 'The Hazard of the Ill' (1902).

Egg, **Augustus Leopold**, English painter: b. London 2 May 1816; d. Algiers, Algeria, 26 March 1863. He became a contributor to the Academy exhibition in 1838, and was elected a member of the Royal Academy in 1860. He painted a great number of pictures illustrative of humorous scenes from Shakespeare, Le Sage, and Walter Scott.

Egg. A cell (ovum) developed in the female reproductive organ (ovary) of any metazoic animal, which, when joined with a male cell (spermatozoön) develops under suitable conditions into an organism like the parents. For the structure of the egg, which differs from other cells only in its germinative property, see CELL; and for its processes of development, see EMBRYOLOGY.

Animals in which the egg passes out of the body before it is hatched, that is, before the maturity and escape of the embryo, are said to "lay eggs," or to be "oviparous"; those in which the egg remains inside the body to hatch are called "ovoviviparous"; those whose eggs are retained in connection with the parent by means of a placenta and an umbilical cord, so that the young are brought forth alive are called "viviparous." These distinctions, and especially the first two, are of secondary importance, and in some cases it is difficult to classify an animal according to them; or varying conditions may lead to change in the same species or individual at different times. A few lowly mammals (the *Monotremes*, q.v.), all birds, and most other animals, "lay" their eggs. The ovoviviparous ones are to be found chiefly among reptiles and fishes.

As in all the higher animals the development of the egg is prolonged, and the young animal must reach a comparatively perfect state of development before it leaves the egg; provision for its nutrition during embryonic development must be made by the storage of food in the egg to be gradually absorbed by the growing embryo; also room for growth, and therefore such eggs are always relatively large. The food is primarily the yolk, which is distinctly yellow in the eggs of birds, reptiles and amphibians, and consists of granules of albuminous and fatty matter perfectly adapted to the nutrition of the young. It lies in concentric layers about the whitish germinal vesicle or "tread" of the egg, which is the protoplasmic part where alone development proceeds. This vesicle floats on the surface of the food-yolk, and remains on top, by reason of its lightness, no matter how the egg is turned. The eggs of many of the lower animals contain food-yolk, but it is usually colorless. The egg of a hen or other bird is further furnished with layers of albumen (the "white") placed upon it in the narrow upper part of the oviduct. Outside of this there is next deposited upon the albumen a fibrous membrane of double thickness (the "egg-pod"), the splitting of which later forms the "air-chamber" at that end of the egg where the head of the chick lies. In a further stage of descent along the oviduct there is deposited in and upon the egg-pod an external covering, or "shell," which may be gelatinous as in the amphibians, or chitinous as among insects, or parchment-like as in reptiles, or calcareous in various degrees, as is familiar in birds' eggs. This shell is porous, so as to admit air to the embryo, which also exposes it to bacteria, so that eggs are liable to quick decay as soon as living influences cease to operate upon it; and preservative methods are directed toward excluding air and germs by closing the pores of the shell. The evil odor of decayed eggs is due to the liberation of sulphuretted hydrogen and certain sulphur proteids, sulphur having a large part in the composition and color of food-yolk. The shells of eggs are often oddly and elegantly shaped, differ greatly in texture and ornamentation, those of insects especially being often exquisitely chased, or studded with projections, and are otherwise beautiful objects under the microscope. Kirby and Spence describe in detail an extraordinary variety, including many which have hinged lids so that the embryo may escape when ready without breaking its way out (see EGG-ROOTER), as do birds and reptiles. The eggs of a great variety

EGGS.

EGGS OF FISHES AND LOWER ANIMALS.

1. Egg of Shark.

2. Egg of Cristiceps.

3. Egg, with embryo of Goby.

4. Spawn of parasitic Fierasfer.

5. Egg with embryo of Stargazer.

6. Egg of Garfish.

7. Spawn of a nudibranch.

8. Spawn of Squid.

9. Spawn of Sea-snail.

10. Spawn of Octopus.

11. Egg of Cuttlefish.

12. Egg of a flat-worm.

13. Egg-capsule of Mantis.

14. The same in cross-section.

15. Egg of a butterfly.

16. Egg of Bedbug.

17. Egg of Beetle-mite.

18. Structure of eggshell of a phyllopod crustacean.

19. Egg of branchiopod crustacean.

EGG

of birds are further ornamented by a uniform tinting or by spottings in diverse patterns and colors, which consist of peculiar pigments, derived from the blood and laid on at the time of the formation of the shell. These color-markings are characteristic of groups to a great extent, and are mainly combinations of yellow, red-brown and greenish-blue. Vast and valuable collections of the nests and eggs of birds exist in museums; and form the topic of the special science oölogy.

Considering the vast variety of animals, and the world-wide diversity of circumstances under which eggs are laid and of conditions which must be met, the greatest dissimilitude is to be expected. In size their range varies from the microscopic cells produced by most mammals to the huge egg of *epyornis* (q.v.), with a capacity of $2\frac{1}{2}$ gallons. The human ovum is among the smallest known, being a minute spherical body from 1-120 of an inch in diameter.

While the eggs of the vertebrates are spherical or nearly so (oblong or oval in various degrees), those of invertebrates often take strange polygonal forms, as is seen among the worms, lower crustaceans, and insects, some of which are illustrated on the accompanying plate. Equally diverse are the methods taken for protection of eggs against harm by weather or enemies, and in proportion as these have proved successful the number laid by each individual is decreased. Many marine animals, such as most worms, echinoderms, coelenterates, bivalve mollusks, and fishes pour out millions of ova, or "spawn," most of which serves only as food for other aquatic animals, probably not a tenth of 1 per cent in many cases ever approaching maturity. Creatures above the rank of the more lowly fishes lay comparatively few eggs—some only one annually. This is also true of certain insects, spiders, crabs, and mollusks, where habits of so hiding or protecting the eggs have been acquired that a large proportion are fertilized and hatched. The methods and adaptations for safety observable among insects are exceedingly varied and effective. Some bury their eggs in the ground, or in dead wood, or living wood, or even in the bodies of dead or living animals; some drop them loose into water, or fasten them to a support under its surface; they hide them in all sorts of crannies, glue them firmly to plants, twigs, rocks, or the skin and hairs of other animals. In the majority of cases this protection must withstand the test of resisting prolonged unfavorable conditions, for most species are preserved from year to year only by the hibernation or estivation of their eggs. Among aquatic animals the encasement of the eggs in a gelatinous envelope, as is so common with frogs, newts, and other amphibians; or a tough capsule, as among the cephalopod and many gasteropod mollusks (for example, *Murex*, *Natica*, *Fusus*) is a common method of protection. These egg-cases are often most curious in form and location.

Economical Value of Eggs.—The eggs of birds, especially of fowls, and of some reptiles, as turtles, are commonly used for food. Boiled eggs are less nutritious because the hardened albumen is with difficulty digested. A hen's egg of good size weighs about 1,000 grains, of which the white constitutes 600, the yolk 300, and the shell 100. There are generally 10.7 parts shell, 11.9 parts albumen, 12.8 parts fat, .7 parts salt,

and 63.9 water. According to Leppig, the specific gravity of fresh eggs is not less than 1.06 grams, and loses 0.0017 grams a day when kept in the open air; so if an egg sinks in a salt solution of 1.05 specific gravity, the egg is fresh. Besides their use as a food, hen's eggs are used in the technical arts, the albumen in which they are so rich being serviceable in dyeing, manufacture of leather, and for various other purposes.

To preserve eggs for any length of time, they must be kept from the air. They may be rubbed over with butter, lard, gum-water, etc., set on the small end upon a perforated board, or, which is still better, they are placed in layers, upon the small end, in very dry ashes, in dry salt, etc., enclosed in tubs and boxes, and put in a dry place, protected from severe cold in winter, but at the same time not too warm.

Eggs are of great importance in a commercial point of view. In England vast quantities are brought from the country to the large towns, but not in sufficient numbers for the demand, and they are largely imported from the Continent, chiefly from France, Germany, Russia, Belgium, and Denmark, also from Canada, the United States, Egypt, Morocco, and other countries. The value of eggs imported into the United Kingdom is more than \$25,000,000 annually.

In the United States the egg industry has grown during recent years to vast proportions. Formerly this country relied largely upon importation for its supply of eggs, but now it exports far more of them than it obtains from foreign parts. The increasing use of incubators has led to a large increase in the number of eggs laid by native fowls, which need "no longer waste their time in hatching them, but may devote it to the more profitable labor of producing them." It is said by experts in this branch of American industry that although the number of fowls kept in this country is now relatively smaller than formerly, yet by the adoption of labor- and time-saving machines the lesser number has been able to produce a constantly increasing output of eggs.

The production of poultry and eggs is one of the most profitable industries. A statistician of authority estimates that a hen may realize 400 per cent profit for her owner. In 33 States and Territories the value of eggs exceeds the value of the poultry product. The egg product in the United States amounts to more, when measured by dollars and cents, than the combined gold and silver production. Prices have not fallen with the introduction of the incubator.

The value of the annual output of eggs is now \$145,000,000. In their production Iowa leads the States, its yearly product being 100,000,000 dozen. Ohio comes next with 91,000,000 dozen; Illinois third, 86,000,000 dozen; and Missouri fourth, 85,000,000 dozen. With the exception of Alaska and Hawaii, Montana pays the highest price for eggs, the average price being 20 cents a dozen. They are cheapest in Texas, where the average price in 1902 was $7\frac{1}{2}$ cents a dozen. The average price for the 16,000,000,000 eggs which were marketed in the United States that year was 11.15 cents a dozen.

The railroad men of the country have an excellent opportunity to measure the extent of the egg industry in concrete exhibits. The annual output fills 43,127,272 crates holding 30 dozen each. An ordinary refrigerator car, which has

EGG—EGGELING

an average length of 42.5 feet, holds 400 crates. It is calculated that a train of these cars sufficient to carry the annual product would be 866 miles long, or long enough to reach from Washington to Chicago, and have several miles to spare. A government expert says: "The majority of the fowls of this country are found in comparatively small numbers on a very large number of farms, where they gather their own subsistence and receive practically no care. The consequence of this is that eggs are produced at little cost. The development of this industry to an extent incredibly larger than it is at the present time is among the easy possibilities."

Egg, or Eigg, ĕg, one of the Hebrides Islands, belonging to Inverness-shire, Scotland. It is south of Skye. Its length is a little less than seven miles.

Egg-bird, or Sooty Tern (*Sterna fuliginosa*), a member of the gull family (*Laridæ*) famous for its edible eggs and breeding societies or "wide-awake fairs." It is found about warm seas throughout the world and abounds in the West Indies. Ascension Island is one of its most frequent breeding places. Occasionally it wanders as far as New England. The adults have beautiful black and white plumage, but the young are of a light, sooty color. The nests are rough excavations in the sand, in which three eggs are usually deposited. They are much valued and the gathering of them in the spring months forms an important West Indian industry. The name egg-bird is also commonly applied to other marine birds of the gull family, as guillemots, murre, etc., whose eggs are of economic value.

Egg Dance, a once popular diversion in England, Scotland, Holland, and some other parts of Europe; now confined chiefly to Spain, among the people of Valencia. A number of eggs were arranged in a prescribed form upon the dancing floor, and among them a blind-folded dancer moved as best he might, to music; the object being to execute an intricate dance without breaking the eggs. The music, like the arrangement of the eggs, was also prescribed.

Egg-eating Snake, the *Dasypheltis scabra*, a tree-climbing species of coluber found in Central and South Africa. It is about two feet in length and is unique in its adaptation to the diet from which it derives its name. While the jaws are almost destitute of teeth and capable of great distention, a substitute for the teeth is found in the elongated hypophyses or ventral processes of several of the cervical vertebrae, which project into the interior of the œsophagus as a series of saw-like teeth tipped with very hard cement substance. This mechanism enables the snake to secure the entire contents of an egg as large as a hen's without losing a drop, for it is swallowed entire and only broken by contact with the œsophageal teeth when safely within the throat, when the contents are swallowed and the shell regurgitated.

Egg-fish, any of various plectognath "globe-fishes," which swell themselves into the shape of an egg. See PLECTOGNATHI; PUFFER.

Egg-flip, a drink made of warmed beer, flavored with a little sugar, spirit, spices, and eggs beaten with it.

Egg-nog, a drink consisting of the yolk of eggs, beaten up with sugar, to which milk is added, and also usually some kind of spirits. By using the whites of the eggs an agreeable froth is made.

Egg-plant, Guinea Squash, or Aubergine (*Solanum melongena*), a plant of the natural order *Solanaceæ*. Its original home is supposed to be the East Indies, where it has long been cultivated and from whence it has been introduced into all tropical countries and many temperate ones for the sake of its egg-like white, yellow, or purple fruits, which are used as a vegetable. In the United States it is cultivated as far north as Long Island and southern Michigan. In the North the plants must be started under glass, and transplanted to the field or garden after danger of frost has passed. They do best upon rich deep loams well exposed to the sun. Their principal insect enemies are practically the same as those of the potato and are combated similarly. (See INSECTICIDE.) Their fungous diseases are few and rarely devastating. The principal ones are a bacterial disease caused by *Bacillus solanacearum*, for which there seems to be no satisfactory remedy; anthracnose (*Glæosporium melongena*), which appears as pink-spotted sunken areas upon the fruits; leaf-spot (*Phyllosticta hortorum*), which turns the affected leaves brown and produces holes in them; and a mold (*Botrytis fascicularis*), which produces soft spots with gray moldy surfaces upon the fruits. Each of these parasites may appear upon any of the green parts, but the parts mentioned are the usual ones. They may all be controlled by timely applications of any standard fungicide.

Egg-tooth, the hard calcareous protuberance at the tip of the beak or snout of a chick or young reptile which is born within an egg having a tough shell, designed to assist the embryo in escaping. It wears a hole through the lining membrane of the egg, and then acts as a file to bore through the outer shell or wedge apart any crack. It is possessed by all birds, and by such reptiles (turtles, lizards, and snakes) as develop in eggs with hard coverings. Soon after the embryo goes free this excrescence falls off; and in this special temporary provision for a special non-recurring exigency, Darwin found an example, in his view, of the results of natural selection.

Egg-urchin, or Sea-egg, any of the typical globose sea-urchins, especially those of the genus *Echinus*. Similarly, the flat, bun-shaped echinoderms are called "cake-urchins," the cockle-shaped (spatangoids) "heart-urchins," and so on. See ECHINODERMATA; SEA-URCHIN.

Egga, ĕg'a, West Africa, town of Gando, in the Niger Territories, on the Niger. Pottery, iron, gold, and wooden-ware, thick cloth, generally dyed blue, and leather are manufactured, and an active river trade is carried on, especially in ivory. Pop. 12,000.

Eggar-moth. See EGGER-MOTH.

Egg'eling, Julius, English philologist: b. Hecklingen, Germany, 12 July 1842. After studying at Breslau and Berlin, he went to England in 1867 and on account of his knowledge of Sanskrit was appointed secretary and librarian of the Royal Asiatic Society 1869, becoming professor of Sanskrit at University College 1872 and

filling the same chair at the University of Edinburgh three years later. Among his publications are 'The Catapatha-Brahmana, Translated according to the Text of the Madhyandina School' (1882-5); 'Catalogue of Buddhist Sanskrit Manuscripts in the Possession of the Royal Asiatic Society' (with Cowell 1875); the article, 'Sanskrit Language and Literature,' in the *Encyclopædia Britannica*; 'Catalogue of Sanskrit Manuscripts in the Library of the India Office' (1887-9); and editions of 'Vardhamana's Ganaratnamahodadhi' (1879-80); the 'Katantra' (1874-8); and of the 'Kanva Satapatha Brahmana' (1902).

Egger-moth, the name of certain species of moth, of the genus *Lasioampa* or *Gastropacha*, allied to the silkworm moths. Several species are found in European countries.

Eggleston, Edward, American novelist and miscellaneous writer: b. Vevay, Ind., 10 Dec. 1837; d. Joshua's Rock, Lake George, N. Y., 3 Sept. 1902. He entered the ministry of the Methodist Church, and was more or less engaged in pastoral work for a number of years, at the same time contributing to various periodicals, for some of which he acted as editor. From 1874 till 1879 he was engaged in the work of an independent church founded by himself (the Church of Christian Endeavor, Brooklyn), but in the latter year his health failed and he resigned his position as pastor. Subsequently he devoted himself entirely to literary work. Among the most important of his works are: 'The Hoosier Schoolmaster' (1871); 'The End of the World' (1872); 'Mystery of Metropolisville' (1873); 'Schoolmaster's Stories for Boys and Girls' (1873); 'The Circuit-Rider' (1874); 'Christ in Literature' (1875, edited); 'Christ in Art' (1875, edited); 'Roxy' (1878); 'The Hoosier School-boy' (1883); 'The Graysons: a Story of Illinois' (1887); 'History of the United States and Its People' (1888); 'Household History of the United States and Its People' (1888); 'The Faith Doctor' (1891); 'Duffels,' a series of short stories (1893); 'The Beginners of a Nation' (1896); and 'The Transit of Civilization' (1900). His work as an historian possessed much merit, in that it was based upon careful investigation and exhibited sound judgment. Yet it is by his early stories of the Middle West that he will always be best known. These stories gave to those who read them at that time a real delight. They were written without the slightest trace of literary art; but their themes were wholly novel, and the unstudied simplicity of their narrator made them so natural and so life-like as at once to charm and surprise all sorts of readers. 'The Hoosier Schoolmaster' may be regarded as the first of a class of stories of which 'David Harum' and 'Eben Holden' are much later examples. The book, in reality, marked a new departure in our national literature; for it owed absolutely nothing to any model, but was a tale told directly from life, and from American life of a primitive kind which had not before made its way into printed books.

Eggleston, George Cary, American journalist and author: b. Vevay, Ind., 26 Nov. 1839. He is a brother of E. Eggleston (q.v.). During the Civil War he served in the Confederate army. He has long been connected in an editorial capacity with one or another New York news-

paper, including the *World*, the *Evening Post*, and the *Commercial Advertiser*. Among his many books are: 'A Man of Honor' (1873); 'A Rebel's Recollections' (1874); 'How to Educate Yourself' (1872); 'How to Make a Living' (1875); 'The Wreck of the Red Bird' (1882); 'Red Eagle'; 'Juggernaut' (with Dolores Marbourg) (1891); 'A Carolina Cavalier' (1901).

Eg'ham, England, village in the County of Surrey, on the Thames, about 21 miles from London. It contains the Royal Indian Engineering College, the Royal Holloway College for Women, and the Holloway Sanatorium. Runnymede, where King John signed Magna Charta, is in Egham parish. Pop. 10,187.

Egil Skallagrimsson, á'gíl skál-lá-grímz'-sôn, Icelandic bard or skald of the 10th century. He distinguished himself by his warlike exploits and adventures in Norway, Denmark, and England. Having killed in combat the son of Erik Blóðöx, king of Norway, he was doomed to death on being subsequently taken prisoner by that prince in Northumbria, but was allowed to redeem his life by giving a specimen of his powers as an improvisatore. He immediately composed and recited a poem in praise of Erik, known as 'Egil's Ransom,' which procured him his life and liberty. This piece (as well as two others attributed to him) is still extant, and Dr. Percy translated it into English, and printed it in his 'Northern Antiquities.' Egil is said to have been born about 901, and to have died about 980, but little dependence can be placed on many of the statements regarding him in the 'Egil's Saga.'

Egilsson, Sveinbjörn, svín'bérn á'gílz'-sôn, Icelandic critic: b. Gullbringasýsla 24 Feb. 1791; d. Reikiavík 17 Aug. 1852. He investigated the native antiquities, edited a series of Icelandic historical works, and completed a 'Poetic Lexicon of the Ancient Tongue of the North' (1855-60), published posthumously.

Eginhard, á'gín-hárd, or **Einhard**, ín'hárd, German historian: b. East Franconia, now the Grand Duchy of Hesse-Darmstadt, about 770; d. Seligenstadt 14 March 840. He was educated in the schools of the abbey of Fulda. When about 25 he entered the service of Charlemagne and thereafter was in all things the confidant of the emperor and one of his principal ministers. One of his great charges was the construction and repair of the public buildings. He was inseparable from the emperor, residing in the palace and accompanying him in all his journeys and expeditions: the only time when they were temporarily separated was when, in 806, the secretary—for such he has always been called—went to Rome to obtain the approval of the Pope of a provision of Charlemagne's testament or will for a division of the empire among his sons after his death. That Eginhard possessed considerable learning appears from his extant writings. During his many years of study at Fulda he acquired all the secular knowledge obtainable in his time, and in the palace of Charlemagne enjoyed the advantage of converse with the celebrated Alcuin. It was on the advice of the secretary that Charlemagne in 813 made his eldest son, Lewis, his partner in the empire; and when Lewis, on his father's death, became sole emperor, he retained Eginhard in all his high offices and appointed him tutor of his son.

Lothair. In 830 he withdrew from the court and retired to his large estates at Mulinheim, where he had erected a splendid basilica and founded various religious institutes, and there passed the remainder of his life. He changed the name of the place to Seligenstadt (City of the Saints, namely, of Saints Marcellinus and Petrus). In this basilica he was entombed, beside his wife, Imma, who died four years before him. According to an old legend Imma was a daughter of Charlemagne, and as time went on the story of their love adventures was added to from the fount of romantic imagination: in fact, Charlemagne had no daughter named Imma, and the lady Imma who was Eginhard's wife was the sister of Bernharius, bishop of Worms. Eginhard's 'Life of Charlemagne' (*Vita Caroli Magni*), written in Latin in a style and on lines imitative of Suetonius' 'Lives of the Cæsars,' is one of the most notable literary monuments of the Middle Ages; it was long used as a manual of school instruction and hence has survived in a multitude of manuscript copies. Another work of his is a history of the Franks, 'Annales Regum Francorum, Pippini, Caroli Magni et Hludowici Imperatoris' (Annals of the Frankish Kings Pippin, Charlemagne, and Lewis the Emperor). There are extant 62 of his 'Letters' (*Epistolæ*), and a narrative of the translation from Rome to Seligenstadt of the relics of Saints Marcellinus and Petrus ('*Historia Translationis Beatorum Christi Martyrum Marcellini et Petri*'). To the narrative he appends a poem on the same subject.

Eglantine, ɛgˈlæn-tin or -tīn, the name of the sweet-brier rose (*Rosa rubiginosa*), in the poetry of Chaucer, Spenser, and Shakespeare. The name is common among the English poets; the earlier ones applied it to any wild rose, and Milton seems to confound several different species, among them the honeysuckle, etc. The flower is a native of Europe and Asia, but was easily naturalized in America and, being hardy, it withstood the severe winters, and now grows in profusion in the territory from Nova Scotia to Ontario, south to Tennessee, and east to the shores of Virginia. It is from 4 to 6 feet high, sometimes growing as a long spine-covered wand. The pink or white flowers are a marked feature of the flora of this region, during the months of June and July. A climbing-shrub, native of Asia (*Rosa eglanteria*), with yellow, ill-smelling flowers, is also sometimes called eglantine.

Eglantine Sponge, a rose gall. See BEDEGNAR.

Egleston, Thomas, American mineralogist: b. New York 9 Dec. 1832; d. there 15 Jan. 1900. He was graduated at Yale College in 1854, and at the School of Mines in Paris in 1860. He returned to the United States in 1861; and soon afterward was appointed director of the mineralogical collection and laboratory of the Smithsonian Institution in Washington. He established the School of Mines as a department of Columbia College, New York; and was professor of mineralogy and metallurgy there 1864-97. He was a United States commissioner to examine the fortifications of the Atlantic coast in 1868; and one of the jurors of the International Exposition at Vienna in 1873. He published: 'The Metallurgy of Gold and Silver in the United States'; 'A Catalogue of Minerals and

Their Synonyms'; 'Life of Major-General Paterson, of the Revolutionary Army'; etc.

Egli, Johann Jakob, yō'hān yā'kōb ā'glē, Swiss geographer: b. Uhwiessen-Laufen, canton of Zürich 17 May 1825; d. 1896. He was made professor of geography at the University of Zürich 1883, after teaching in several schools, and did much for the accuracy, precision and uniformity of the nomenclature of geography. Among his earlier works are a thesis on the 'Discovery of the Sources of the Nile'; and a 'Geography of Switzerland.' Later works include 'Nomina Geographica: Versuch einer allgemeinen geographischen Onomatologie'; 'Geschichte der geographischen Namenkunde'; 'Neue Erdkunde'; 'Neue Handelsgeographie'; and 'Der Völkerggeist in den geographischen Namen.'

Eglington and Winton, Archibald William Montgomerie, EARL OF, English politician: b. Palermo, Sicily, 29 Sept. 1812; d. St. Andrews, Scotland, 4 Oct. 1861. He was lord-lieutenant of Ireland in 1852, and 1858-9. He was a well-known patron of the turf and field sports, and his name is associated with a splendid reproduction of a mediæval tournament, which he gave at Eglington Castle in 1839.

Eg'mont, Justus van, Flemish painter: b. Leyden 1602; d. Antwerp 8 Jan. 1674. He was a pupil of Kaspar Van den Hoeck 1651 and later of Rubens. He established himself at Paris where he became court painter to Louis XIII. and Louis XIV., and was also one of the founders of the Royal Academy of Painting and Sculpture 1648. Among his works are: 'Portrait of Archduke Leopold William'; two 'Portraits of Philip IV. of Spain,' Vienna Museum; 'Maria de Medici,' Schleissheim Gallery; and 'Portrait of Queen Christine.'

Eg'mont, Lamoral, Count, Dutch statesman: b. La Hamaide, Hainault, 18 Nov. 1522; d. Brussels 5 June 1588. He entered the military service, and gained a high reputation under Charles V.; distinguished himself as general of cavalry under Philip II.; and was made stadtholder of the provinces of Flanders and Artois. His connection with the Prince of Orange and his most distinguished adherents made him an object of suspicion to the Spanish court, and Egmont, with Philip of Montmorency, Count Hoorn, became the victims of hate and fanaticism. The Duke of Alba, sent by Philip II. to the Netherlands in 1567 to reduce the insurgents, had Egmont and Hoorn treacherously seized, and caused them both to be executed at Brussels. Egmont died with heroic firmness. He had before written to Philip II., that "he had never joined in any undertaking against the Catholic religion, nor violated his duties as a loyal subject." But the Prince of Orange having taken the field as the champion of his country's wrongs, an example was thought necessary to strike terror into the insurgents. There can be little doubt that the Spanish king unnecessarily dreaded the influence of the gallant soldier but incapable politician. When the troubles in the Netherlands broke out, Egmont, moved by generous sympathy for his injured countrymen, rather than by any fixed principle of action, was found side by side with the Prince of Orange, in the van of the malcontents. But in opposition to the popular movement came his strong feeling of

EGMONT—EGYPT

loyalty to Spain, and his still stronger devotion to the Roman Catholic faith. Thus, the opposite forces by which he was impelled neutralized each other, and, ever acting from impulse, he did not calculate the consequences of his conduct. When these consequences came he was not prepared to meet them. See Motley, 'Rise of the Dutch Republic'; Juste, 'Le Comte d'Egmont et le Comte Hoorn' (1862); Goethe, 'Egmont,' a drama.

Egmont. See PORT EGMONT.

Egoism, ē'gō-izm (Fr. *égoïsme*; Lat. *ego*, "I"), an ethical term used in the sense of selfishness; it is specially opposed to altruism. The word is sometimes used to denote a metaphysical system of subjective idealism, in which the Ego is the sole reality. See ALTRUISM; ETHICS.

E'goist, The, a novel by George Meredith, published 1879. It describes the experiences of Sir Willoughby Patterne, of Patterne, in selecting a wife.

Egret, ē'grēt, a name given to those species of white herons which have the feathers of the lower part of the back elongated and their webs disunited owing to the absence of barbs at certain seasons of the year, that they form a soft and flowing train reaching to the tail or beyond it. Their forms are more graceful than those of the common herons. The name is properly applied to two American and two European species. The American egret (*Ardca egretta*) has the plumage white, or partly of a creamy color. The bird is found breeding from Florida to New York, and along the shores of the Mexican Gulf to Texas, but ranges much beyond these limits at other seasons. Its food consists of the smaller quadrupeds, small fishes, frogs, lizards, snakes, and insects, and it breeds like other herons. The long silky filaments of the back are hardly to be seen, except about the love season, which varies from early spring to mid-summer according to climate; both sexes possess this train, and many are shot to obtain these feathers for ornamental purposes. The little white egret or snowy heron of America (*A. candidissima*) is much smaller and has a crest on the head which the large species lacks. In habits and distribution it is similar. The European egret (*A. alba*) is about 40 inches long, of a pure white plumage. It is common in southern Europe, but comparatively rare in the northern and central parts. The little egret (*A. garsetta*) is about 22 inches long from bill to end of tail; the plumage is white; from the hinder part of the head spring two narrow feathers four inches long. This species is most abundant in southern Europe and northern Africa; it occasionally wanders as far as England. The Louisiana heron (*A. tricolor*) and the reddish egret (*A. rufescens*) are often given the name, but the latter is white in winter only, and the former is partly colored at all seasons. Both are maritime birds, chiefly of the Gulf States.

Egusquiza, Juan Batista, hoo ān' bā-tēs'-tā ā-goos-kē'thā, Paraguayan statesman: b. Asuncion 1845. He was a lieutenant-colonel in the war with Uruguay, Brazil, and the Argentine republic, later being appointed secretary of war, and attaining the rank of general. He was elected president of Paraguay 1894.

Eguzquiza, ā-gooth-kē'thā, Rogliode, Spanish painter: b. Santander 1835. He studied at

the Ecole des Beaux Arts, Paris. Among his works are: 'Virgin with Rosary' (1859); 'Discussion Between Don Quixote and the Cure'; 'Michelangelo Beside the Body of Vittoria Colonna'; 'Charles V. at Convent of St. Juste' (1868), reproduced in popular engraving; 'Family Concert'; 'Master-at-Arms'; 'Portrait of Lady' (1878).

Egypt (in Greek *Aiguptos*; in Hebrew, *Misr* or *Misraim*; in the language of the country in hieroglyphics, *Kemi*—which signifies the black land; and by the Arabs of the present day called *Misr*), a country in the northeastern part of Africa. Egypt proper extends from the Mediterranean Sea south to lat 22° N., and from thence southward into equatorial Africa, which latter region, known as the Egyptian Sudan, is governed by Egypt and Great Britain jointly. The eastern boundary is the Red Sea, and on the extreme northeast Syria. The western boundary runs northwest to Tripoli, and thence southeast to a point 200 miles west of Wady-Halfa. One third of the Libyan Desert also belongs to Egypt. The area of Egypt is about 400,000 square miles, the country extending 675 miles north and south, and 500 miles east and west. Its population is about 11,000,000.

Topography.—In ancient as in modern times Egypt was always divided into the Upper and the Lower, or the Southern and the Northern, country; and at a very early period it was further subdivided into a number of *nomes*, or departments, varying in different ages; 42 was probably the usual number. A third great division, the *Heptanomis*, or seven nomes, preserved in the modern "Middle Egypt" (*Wustāni*), was introduced at the time of the geographer Ptolemy. Each nome or department had a separate local government. In the 5th century A.D. Egypt was divided into Augusta Prima and Secunda on the east, and Ægyptiaca on the west, Arcadia (the Heptanomis), Thebais Proxima as far as Panapolis, and Thebais Supra to Philæ. Under the Mohammedans, the triple division into Misr el-Bahri (Lower Egypt), el-Wustāni (Middle), and es-Sa'id (Upper) has prevailed, but the number of subdivisions has varied; at present there are altogether thirteen provinces. Egypt is connected with Asia by the isthmus of Suez, across which runs the great canal, about 100 miles long. The inhabited portion of Egypt is mainly confined to the valley and delta of the Nile, which where widest does not exceed 120 miles, while in many parts of the valley it is only from 10 to 15 miles wide, at the southern frontier of Egypt only two miles. West of the Nile are several oases. Two ranges of lofty mountains, the Arabian Hills on the east and the Libyan on the west, enclose this valley. The delta of the Nile is traversed by a network of primary and secondary channels, and is also intersected by numerous canals. Seven principal channels or mouths were usually recognized in ancient times, the names of which, going from east to west, were the Pelusiatic mouth, the Tanitic, the Mendesian, the Phatnitic (Damietta), the Sebennytic, the Bolbitic (Rosetta), and the Canopic. The Nile has a current running seaward at the rate of 2½ or 3 miles an hour, and the stream is always deep enough for navigation. The water becomes a reddish brown during the annual overflow; it is esteemed highly salubrious. Near the sea are Lake Menzaleh

EGYPT

Mariut (Mareotis), and other extensive but shallow lagoons. The openings or lateral valleys of the hills confining the valley of the Nile are comparatively few, or, being little frequented, are not well known. Those on the east side with which we are best acquainted are the Valley of the Wanderings (of the children of Israel), leading from the neighborhood of Cairo to the head of the Gulf of Suez, and that through which passes the road from Koptos to Kosseir on the Red Sea. A short distance west of the Nile and above the delta is the fertile valley of Fayoum in the northwest and lowest part of which is the Birket-Karun Lake or Birket-el-Kerûn, fed by a canal or branch from the Nile. The level of the lake is now 130 feet below that of the Mediterranean. This lake, formerly known as Lake Meris, anciently covered a far larger area, and by means of sluices and other works was utilized for irrigation purposes. The deserts on the west bank of the Nile generally present to view plains of gravel or of fine drifting sand; on the east the scene is varied by rocks and mountains.

Climate.—The atmosphere in Egypt is extremely clear and dry, the temperature regular and hot, though the heat is tempered during the daytime for seven or eight months of the year by the strong wind which blows from the north, and which enables sailing vessels to ascend the river against the stream. The winter months are the most delightful of the year, the air being cool and balmy, and the ground covered with verdure; later, the ground becomes parched and dry, and in spring the suffocating *khamsen*, or simoom, frequently blows into the Nile valley from the desert plains on each side of it, raising clouds of fine sand, and causing great annoyance, until the rising of the river again comes to bless the land. It rains but rarely, except near the sea-shore. At Memphis the rain falls perhaps three or four times in the course of a year, and in Upper Egypt only once or twice, if at all; showers of hail sometimes reach the borders of Egypt, but the formation of ice is very uncommon. Earthquakes are occasionally felt, and thunder and lightning are neither frequent nor violent. Egypt is not remarkably healthy, especially in the delta, ophthalmia, diarrhœa, dysentery, and boils being somewhat prevalent. But many invalids now winter in Egypt, especially in the neighborhood of Cairo, or higher up the river, where the air is dry and pure.

The Nile and Irrigation.—The great historic river Nile, anciently called the Nilus, is 3,400 miles in length, the longest in Africa and one of the few great rivers of the world. It divides, at lat. 30° 15', just below the First Cataract, into two main streams, the one entering the sea by the Rosetta mouth on the west, the other by the Damietta mouth on the east. These two streams carry the bulk of the Nile water to the Mediterranean, and inclose a large portion of the territory known as the delta, from its resemblance to the Greek letter Δ and which owes its existence to the deposits of alluvial matter brought down by the stream. The most remarkable phenomenon connected with the Nile is its annual regular increase, arising from the periodical rains which fall within the equatorial regions and the Abyssinian Mountains. As rain rarely falls in Egypt, the prosperity of the country entirely depends on this overflowing of the river. On the subsiding of the water the land is

found to be covered with a brown slimy deposit, which so enriches the soil that with a sufficiency of water it produces two crops a year, while beyond the limits of the inundation and irrigation there is no cultivation whatever. The Nile begins to rise in June, and continues to increase until about the end of September, overflowing the low lands along its course, the water being conveyed to the fields by artificial courses where natural channels fail. After remaining stationary for a short time, the river rises again still further, but subsequently begins to subside, showing a markedly lower level in January, February, and March, and reaching its lowest in April, May, and early June. The overflow water is now to a great extent managed artificially by means of an extensive system of reservoirs and canals, so that after the river subsides it may be used as required. A certain proportion of the fields, after receiving the overflow and being sown, can ripen the crop without further moisture; but many others always require artificial irrigation. Steam pumps are now largely used in northern Egypt. Latterly the government has tried to make the farmers less and less directly dependent on the inundation, and the great barrage of the Nile below Cairo, the largest weir in the world, is one means to this end, the great dam or barrage at Assouan being another.

The native methods of raising water for irrigation are chiefly by the *sakieh*, or water wheel, and the *shadouf*. The first consists of a horizontal wheel turned by one or two oxen, which sets in motion a vertical wheel, around which are hung a number of earthen jars, this wheel being sunk into a reservoir connected with the river. The jars thus scoop up the water and bring it to a trough on a level with the top. Into this trough each jar empties itself in succession, and the water is conducted by an inclined channel into the cultivated ground adjoining, which may have been previously divided into compartments of 1 or 2 yards square by raising the mold into walls or ridges of 5 or 6 inches in height. Into these compartments the cultivator forms an entrance for the water, by depressing a little space in the ridge or wall with the sole of his foot; and this overlooking of the channels of irrigation, and adjustment of the openings from one compartment to the other with the foot, is continued till the cultivator is assured by the growth of the plants that each compartment is daily and duly supplied with its proper quantity of water. The second means of raising water, namely, the *shadouf*, consists of a leathern bucket slung at one end of a pole which has a weight at the other and sways up and down on a vertical support, a contrivance by which the cultivator is enabled to scoop up the water considerably below his feet, and raise it with comparative ease to the mouth of a channel on a level with his breast. The latter mode of raising water is of great antiquity, and is depicted on the walls of the ancient tombs of Egypt, and also in the sculptures from Nineveh. A sufficient rise of the river (the rise varies at different points) is essential to secure the prosperity of the country; and as the water subsides, the chaplet of buckets on the *sakieh* is lengthened, or several *shadoufs*, rising one above the other on the river bank, are required. Should the Nile rise above the requisite height it may do great damage; while if it should not attain the

EGYPT

ordinary height, there is a deficiency of crops; but so regular are the operations of nature that, with rare exceptions, the inundations are nearly uniform. See DELTA; IRRIGATION; RIVER.

Oases.—The fertile spots peculiar to the deserts of Africa are found in Egypt along the hollow region of the Libyan Desert, parallel to the general direction of the valley of the Nile, and above 80 miles west of it. The Great Oasis, or El Wah (the oasis), el Khargeh, lies immediately west of the Thebaid, and has a length of 100 miles. About 50 miles west of the northern extremity of this oasis lies the Wah el Dakhileh, 24 miles long and 10 miles broad. West by south from the Fayoum the date groves of the Little Oasis, or Wah el Baharieh, display their unusual verdure. In this fertile spot artesian wells are numerous, and some of ancient construction have been discovered which have a depth exceeding 400 feet. On the road between this oasis and that of El Dakhileh, inclining to the west, occurs half-way the Wah el Farafrah, of small extent. West of the Fayoum, and about 200 miles from the Nile, lies the oasis of Siwah. The inhabitants of this secluded spot, though tributary to Egypt, are in language and manners wholly Libyan. The region of the oases terminates toward the north in the desert of the Natron lakes. See OASIS.

Zoology.—Owing to the absence of forests in Egypt there are few wild animals, the principal species being the wolf, fox, jackal, hyena, the wild ass, and several kinds of antelope. The chief domestic animals are camels, horses, asses, horned cattle, and sheep. The hippopotamus is no longer found in Egypt, though it is met with in the Nile above the cataracts, and the crocodile has abandoned the lower part of the river, and is becoming rare even in Upper Egypt. Among the birds are three species of vultures (one of which is very large, individuals sometimes measuring 15 feet across the wings), eagles, falcons, hawks, buzzards, kites, crows, linnets, larks, sparrows and the beautiful hoopoe, which is regarded with superstitious reverence. Pigeons and various kinds of poultry are very abundant. The ostrich is found in the deserts. Among the reptiles are the cerastes and naja haje, both deadly poisonous. Fishes abound in the Nile and in the lakes, and furnish a common and favorite article of food. Water-fowl are plentiful, and were anciently prepared and salted like fish. The sacred ibis is still a regular visitor during the inundation, and the pelican is found in the northern lagoons. Among the countless insects are the sacred beetle, the locust, and mosquito. Many of the animals, birds, and reptiles were held sacred by the people; whoever killed a sacred animal, an ibis or a hawk, was put to death. If a cat died a natural death every person in the house shaved his eyebrows; if a dog died, the whole body and the head were shaved. The cats were buried at Bubastis, the dogs in the vaults of their own cities, field-mice and hawks at Buto, the ibis at Hermopolis, and other animals where they were found lying. Of all animals the sacred calf Apis was the most revered. His chief temple was at Memphis. The females, being sacred to Isis, were thrown into the Nile, which was considered sacred, and the males were buried at Sakkara.

Botany.—The few trees found in Egypt include the date-palm, tamarisk, sycamore,

Christ's-thorn, carob, and two species of acacia. Many trees have been planted in recent times, especially about Cairo, such as the lebbek (*Albizia Lebbek*) and the eucalyptus. The papyrus plant, once so important, is now to be found only in one or two spots. Of it was manufactured a paper, which was supplied to all the ancient world. Boats, baskets, cords, and shoes were also made of it. Wine was abundantly produced in ancient Egypt, and the sculptures bear ample testimony to the extent to which the ancient Egyptians indulged in wine and beer or other intoxicating beverages. The vine is still much cultivated, but little or no wine is made, as it can easily be imported. The following plants are sown immediately after the inundation begins to subside, and are harvested three or four months later: wheat, barley, beans, peas, lentils, vetches, lupins, clover, flax, lettuce, hemp, coriander, poppies, tobacco, watermelons, and cucumbers. The following plants are raised in summer chiefly by artificial irrigation: durra, maize, onions, henna, sugarcane, cotton, coffee, indigo, and madder. Grapes are plentiful, and other fruits abound, of which the most common are dates, figs, pomegranates, apricots, peaches, oranges, lemons, citrons, bananas, mulberries, and olives. The lotus or water-lily is the chief species of flora found in Egypt. There is a high coarse grass called halfa and various kinds of reeds and canes.

Geology and Mineralogy.—Granite, limestone and sandstone are the principal rock formations found in Egypt. In the Nile Valley sandstone prevails, from the quarries of which most of the temples of Egypt have been built. At Syene, at the southern extremity of the country, granite predominates, and the quarries there have furnished chiefly the materials for the obelisks and colossal statues of Egypt. Over a great extent of the country the rocks are covered with moving sands, and in the lands bordering on the Nile by the alluvium deposited during the inundations, which consists of an argillaceous earth or loam, more or less mixed with sand. This sedimentary deposit has no traces of stratification. Various other minerals in addition to those already mentioned, and which were used in the ancient buildings, sculpture, vases, etc., include syenite, basalt, alabaster, breccia, and porphyry. Among other valuable products were emeralds, gold from the mines in Upper Egypt, iron from the desert plains of Nubia, and natron from the lakes in the Oasis of Ammon, hence called sal-ammoniac. Bitumen, salt, and sulphur are also among the minerals of Egypt.

Inhabitants.—Of the inhabitants of Egypt those of the peasant class, or Fellahs, as they are called, are undoubtedly indigenous, and may be regarded as descendants of the ancient Egyptians. They have mostly embraced Mohammedanism. The Copts are the descendants of the ancient Egyptians who embraced and still cling to the Christian religion. Though comparatively few in number (about 600,000), their education and useful talents enable them to hold a respectable position in society. The Fellahs are generally peasants and laborers; the Copts fill the posts of clerks, accountants, etc. With these aboriginal inhabitants are mingled, in various proportions, Turks, Arabs (partly Bedouins), Armenians, Berbers, negroes, and a considerable number of Europeans. The Turks hold many of

EGYPT

the principal offices under the government. The great bulk of the people are Mohammedans, the Christians being only about 7.5 per cent. The Egyptians in the mass are quite illiterate, but under the supervision of the ministry of public instruction progress is being made. In 1902 there were about 10,000 schools with 228,000 pupils. The language in general use is Arabic.

The Fellahs, the most superior type of the Egyptian, are a fine race, handsome, of excellent physique, and courteous in their manners. In northern Egypt they are of a yellowish complexion, growing darker toward the south, until the hue becomes a deep bronze. Mr. Lane, the best authority upon the subject, speaks highly of their mental capacity, and gives them credit for uncommon quickness of apprehension and readiness of wit. They are highly religious, and are generally honest, cheerful, humane, and hospitable. But these are exceptions in a mixed population of Bedouins, negroes, Abyssinians, Turks, Syrians, Greeks, Armenians, Jews, and Europeans. The dominant population appears, from the language, and from the physical conformation of the mummies, to have been of mixed origin, part Asiatic and part Nigritic; and there seems to have been an aboriginal race of copper color, with rather thin legs, large feet, high cheek-bones, and large lips; both types are represented on the monuments. The statements of Greek writers that a system of castes prevailed in Egypt are erroneous. What they took for castes were really conditions of society, and the different classes not only intermarried, but even, as in the case of priests and soldiers, held both employments. As in all bureaucracies, the sons often obtained the same employments as their fathers. The population must have been very large at the earliest period, as 100,000 men were employed in the construction of the Great Pyramid alone during the 4th dynasty, nearly 3600 years B.C. It has been placed at 7,000,000 under the Pharaohs, distributed in 1,800 towns, which had increased to 2,000 under Amasis (525 B.C.), and upwards of 3,000 under the Ptolemies. In the reign of Nero it amounted to 7,800,000. The population in 1844 was 2,500,000; in 1859, 5,125,000; in 1882, 6,817,265, and in 1897, 9,734,405. The population in 1903 is estimated at 11,000,000, which includes 40,175 Greeks, 24,467 Italians, 19,557 British, and 18,155 French. The chief towns of Egypt proper are Cairo (pop. 600,000); Alexandria (250,000); Damietta (35,000); Tantah (34,000); Assiout (32,000); Mansourah (27,000); Fayoum (26,000); Damanhour (24,000); Zagazig (19,000); Rosetta (17,000); Port Saïd (16,500); Suez (11,000). See BEDOUINS; COPTS; FELLAHS.

Government.—The ancient government of Egypt was a monarchy, limited by strict laws and by the influence of powerful hereditary privileged classes of priests and soldiers. The priests were the ruling class. They were restricted to a single wife, and if polygamy was permitted to the rest of the people, it must have been very seldom practised. The marriage of brothers and sisters was permitted. The laws were wise and equitable, and appear to have been rigidly enforced. Murder was punished with death, adultery by bastinadoing the man and by cutting off the nose of the woman, forgery by cutting off the culprit's hands. Imprisonment for debt was not permitted, but a man could pledge to his creditors the mummies

of his ancestors, and if he failed in his lifetime to redeem them, he was himself deprived of burial. Women were treated with respect, and the laws and customs seem to have been so favorable to them that their condition in Egypt was much higher than in any other nation of antiquity. The military force of Egypt was a species of hereditary militia, which formed one of the leading classes or castes, and in time of peace cultivated the land, of which it held a large portion. The king's guards, some few thousands in number, were the only standing army. The number of soldiers in the military caste is stated by Herodotus at 410,000, which probably included all the men of that class able to bear arms. It is not probable that the whole of them ever were or could be brought into the field at once. Their arms were spears and swords, and they were protected by large shields.

At the present day the government is in the hands of the viceroy or khedive, as supreme ruler, who pays an annual tribute of about \$3,000,000 to Turkey, and is assisted by a ministry formed on the model of those of western Europe. The capital is Cairo. The government is carried on under the supervision of Great Britain, the rebellion of Arabi Pasha in 1882 having been put down and the authority of the khedive restored by British troops. For some years previous to this two controllers-general, appointed respectively by France and Britain, had extensive powers of control in the administration of the country. The British have initiated various reforms in the administration, such as the establishment of new native tribunals. The administration of justice is somewhat complicated, there being native tribunals, consular courts, mixed tribunals, and religious courts. The financial condition of Egypt is being slowly improved under British management. The Egyptian army is under the command of an English general, and officered partly by Englishmen and partly by Egyptians; its total strength is 18,100, while the English army of occupation, which, since the rebellion of 1882, has remained in Egypt, has a strength of 5,600.

Commerce and Industry.—Agriculture, manufacture and trade were carried on in Egypt in the very earliest days. Upon the ancient monuments we find representations of the mechanical arts, and we see the blow-pipe, bellows, and siphons; the press, balance, lever, the saw, the adze, the chisel, the forceps, the syringe, harpoon, razors; we have also glazed pottery, the potter's wheel, and the kiln; and dated specimens of glass of the time of Thothmes III. (1445 B.C.) Gold-beating, damascening, engraving, casting, inlaying, enameling, wire-drawing, and other processes were practised. In warfare, shields, cuirasses of quilted leather, helmets, spears, clubs, maces, daggers, bows, battle-axes, pole-axes, hatchets, and falchions; for sieges the testudo, ladders, torches, and lanterns were in use. In agriculture the plough, hoe, sickle, and other implements were employed. The processes of growing and preparing flax, and making it into thread, string, ropes, and cloth, as well as the looms employed, are all depicted. Mats and baskets were beautifully made, either of the halfa grass or palm leaves, or of the outer rind of the papyrus plant, which was used in making paper. Coffins or wooden sarcophagi were chiefly of sycamore or

EGYPT

cedar, covered with stucco and richly painted. The ordinary boats of the Nile were of planks of the acacia, and had two rudders or large oars, with a sail of cloth frequently painted or worked in colored patterns. Many of the vessels of burden were of great size. The boats made of papyrus were mostly punts for fishing, or for gliding through the canals of the Delta. Implements for painting, ladles, bells, crucibles, and surgical instruments have also been found. The commerce of the Egyptians with neighboring nations enriched the country with slaves, cattle, gems, metals, rare animals, and objects of curiosity. The Egyptians expended enormous wealth on the tombs and furniture of the dead, and the paintings acquaint us fully with the various ceremonies followed. In embalming they excelled.

To-day the one branch of industry for which Egypt is peculiarly adapted by nature is agriculture, and large quantities of cereals, cotton, and other agricultural produce are raised; yet, generally speaking, agriculture is still in a very low state, the necessary consequence of the wretched condition and extreme poverty of those engaged in it. The Egyptians still adhere to their ancient custom of uniting the followers of each business or profession into a guild, governed by their sheikh, who acts, if need be, as their representative. These guilds are exceedingly numerous, as might be expected among a people whose social organization dates from a remote antiquity.

Among the crops which the Egyptians grow with success, cotton is the most popular and profitable. (See *COTTON*.) The cotton plant of Egypt differs materially, in one respect at least, from that of other countries. In America it has been found unprofitable to allow the plants to continue in the ground longer than one year. In Egypt, however, the case is different, for the cotton plant yields five, and sometimes six, consecutive crops before replanting is found to be necessary. This being the case, a cotton field once planted is a secure investment for at least five years, and as peasants of the Nile do not love labor, more cotton is grown in Egypt in proportion to the population engaged in agriculture than in any other part of the world. In both Upper and Lower Egypt cotton is therefore the standard crop, and as it is not troubled with worms as in America, and by the method of irrigation the farmer can give it exactly the right portion of moisture and no more, the crop is tolerably reliable. The boats transport the product to Cairo or to Alexandria, the leading cotton markets. The exchange in the former city is located on one of the principal streets, while the market proper is in a public square opposite the great Mosque of Hassan. The time of the river journey to Alexandria is from six days to six months, for, as the Mohammedans say, "God is great, and there is no hurry."

The business of tanning also is one in which the Egyptians succeed perfectly, by a process peculiar to themselves. They make excellent morocco leather, which is goatskin dressed and dyed in a particular manner. The pottery of Egypt also deserves a word of praise, chiefly for the merit of the bardaks or water-jars. Coarse cotton cloths, and cloths of mixed cotton and wool, are largely made in the country; silk is cultivated to some extent; and the cultivation of the sugarcane received a great im-

pulse from the viceroy, Ismail, who erected a number of mills at great expense. Goods carried by the Suez Canal do not form part of the commerce of the country, and the transit trade proper is of little importance. The exports of Egypt for 1902 amounted to £19,451,460 and the imports £16,649,145. The public debt (1901) amounts to £103,264,540. The railway system, under government control, embraces 2,173 miles and nearly 2,877 miles of telegraph lines.

History.—The history of Egypt, prior to the beginning of the ancient empire 4000 B.C., is entirely mythical. The history divides itself into six great periods: (1) The Pharaohs or native kings; (2) the Persians; (3) the Ptolemies; (4) the Romans; (5) the Arabs; (6) the Turks.

The main sources of its history under the Pharaohs are the Scriptures, the Greek writers Herodotus, Diodorus, and Eratosthenes, some fragments of the writings of Manetho, an Egyptian priest in the 3rd century B.C. From the Scriptures we learn that the Hebrew patriarch Abraham went into Egypt with his family because of a famine that prevailed in Canaan. He found the country ruled by a Pharaoh, the Egyptian term for king. The date of Abraham's visit, according to the chronology of the Hebrew text of the Bible, was 1920 B.C.; according to the Septuagint, 2551; while Bunsen fixes it at 2876. Nearly two centuries later Joseph, a descendant of Abraham, was sold into Egypt as a slave to the captain of the guards of another Pharaoh, whose prime minister or grand vizier the young Hebrew eventually became. Joseph's father, Jacob, and his family, to the number of 70, accompanied, as Bunsen conjectures, by 1,000 or 2,000 dependents, followed their fortunate kinsman into Egypt, where they settled in a district called the land of Goshen. There they remained until their numbers had multiplied into two or three millions, when under the lead of Moses they revolted and quitted Egypt to conquer Canaan.

Menes was the first king of Egypt, and was succeeded by 330 monarchs, of whom one, Nitocris, was a queen. None of them were distinguished, and none of them left any monuments worthy of note, except Moeris, the last of the 330, who constructed the artificial lake which bears his name. He was succeeded by Sesostris, who conquered Ethiopia and the greater part of Europe and Asia. His successors were Pheron, Proteus (who was contemporary with the Trojan war), Rhampsinitus, Cheops, Cephren, and Mycerinus. The last three kings built the three great pyramids. Mycerinus was succeeded by Asychis, and Asychis by Anysis, in whose reign Egypt was conquered by the Ethiopians, who held it for 50 years under King Sabaco. At the expiration of the half century they voluntarily abandoned the country and retired to Ethiopia. The next king of Egypt was Sethos, between whom and the first king Menes, the priests told Herodotus, there had been 341 generations, a period of 11,340 years. Sethos was succeeded by 12 kings, who reigned jointly, and together built the Labyrinth, which Herodotus thought surpassed all the works of the Greeks. After the lapse of some years, Psammetichus, one of the 12 kings, dethroned the others and made himself sole sovereign of Egypt. He was succeeded by Necho, Psammis, and Apries, the last of whom Herodotus calls

EGYPT

the most prosperous king that ever ruled over Egypt. But in the 25th year of his reign a rebellion broke out which was headed by Amasis. Apries was defeated and put to death, and Amasis became king. Amasis was succeeded by his son Psammenitus, at the very beginning of whose reign, 525 B.C., Egypt was invaded and conquered by the Persians under Cambyses.

Cambyses treated Egypt with considerable moderation, but after an unsuccessful expedition against the Ethiopians, lost his reason, stabbed the bull Apis, and committed various atrocities. His successor, Darius I., governed Egypt with more prudence; but Xerxes I. and Artaxerxes I. had successively to reduce it to subjection, which they did in spite of assistance rendered to it by the Athenians. The 27th dynasty of Persians was followed by another Saïte line, the 28th, who still held ground against the Persians. The 29th, Mendesian, dynasty of Nephherches and Achoris maintained a Greek alliance; and the 30th, Sebennytic, consisted of Nectanebes I., who successfully resisted Pharnabazus and Iphicrates, of Teos, who employed Agesilaus, and of Nectanebes II., who fled into Ethiopia before the Persians (340 B.C.). In 332 B.C. the Persians were driven out by Alexander the Great, with whom begins a new period, the Græco-Roman, in the history of the country.

When Alexander's army occupied Memphis the numerous Greeks who had settled in Lower Egypt found themselves the ruling class. Egypt became at once a Greek kingdom, and Alexander showed his wisdom in the regulations by which he guarded the prejudices and religion of the Egyptians. He founded Alexandria as the Greek capital, and this city became the great centre of commerce and Greek civilization that it long continued to be. The court of the Ptolemies became the centre of learning and philosophy; and Ptolemy Philadelphus, successful in his external wars, built the Museum, founded the library of Alexandria, purchased the most valuable manuscripts, engaged the most celebrated professors, and had the Septuagint translation made of the Hebrew Scriptures, and the Egyptian history of Manetho drawn up. His successor, Euergetes, pushed the southern limits of his empire to Axum. Philopator (221-204 B.C.) warred with Antiochus, persecuted the Jews, and encouraged learning. Epiphanes (204-180 B.C.) encountered repeated rebellions, and was succeeded by Philometor (180-145 B.C.) and Euergetes II. (145-116 B.C.), by Soter II. and Cleopatra till 106 B.C., and by Alexander (87 B.C.), under whom Thebes rebelled; then by Cleopatra Berenice, Alexander II. (80 B.C.), and Neos Dionysus (51 B.C.), and finally by the celebrated Cleopatra. After the battle of Actium (31 B.C.) Egypt passed into the condition of a province of Rome, governed always by a Roman governor of the equestrian, not senatorial, rank. The Egyptians had continued building temples and covering them with hieroglyphics as of old; but on the spread of Christianity the older religions lost their sway. Now arose in Alexandria the Christian catechetical school, which produced Clemens and Origen. Monasteries were built all over Egypt; Christian monks took the place of the pagan hermits, and the Bible was translated into Coptic.

On the division of the great Roman empire (337 A.D.), in the time of Theodosius, into the Western and Eastern empires, Egypt became a province of the latter, and sank deeper and deeper in barbarism and weakness. It then became the prey of the Saracens, Amru, their general, under the Caliph Omar, taking Alexandria, the capital by assault. This happened 640 A.D., when Heraclius was the emperor of the East. As a province of the caliphs, it was under the government of the celebrated Abbassides—Harun al-Rashid and Al-Mamon—and that of the heroic Sultan Saladin. The last dynasty was, however, overthrown by the Mamelukes (1240), and under these formidable despots the last shadow of former greatness and civilization disappeared. Selim Sultan of the Turks, eventually (1516-17) conquered the last Mameluke sultan, and Egypt became altogether a Turkish province, governed by a pasha. After this it was the theatre of internal wars by the Mameluke beys against the Turkish dominion, which was several times nearly extinguished. Confusion and civil war between the different factions of the Mamelukes continued to prevail till 1798, when the French invasion under Napoleon Bonaparte united their chiefs in self-defense; but the Mameluke army was all but annihilated in the battle of the Pyramids. The French now conquered the whole of Egypt and held it till 1801, when they were driven out by the British under Abercromby and Hutchinson.

On the expulsion of the French the Ottoman porte effectually urged its claim to sovereignty, and the accession of the Albanian soldier, Mohammed 'Ali to the pashalik in 1805 imparted a galvanic prosperity to Egypt, by the merciless destruction of the turbulent Mamelukes (whom a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation, and the introduction of the elements of European civilization. In 1816 Mohammed 'Ali reduced part of Arabia to his sway by the generalship of his son, Ibrahim; in 1820 he annexed Nubia and part of the Sudan, and from 1821 to 1828 his troops, under Ibrahim, occupied various points in the Morea and Crete, to aid the Turks in their war with the insurgent Greeks. The Egyptian fleet was annihilated at Navarino, and Ibrahim remained in the Morea till forced to evacuate by the French army, under Maison, in 1828. In 1831 Ibrahim began the conquest of Syria, and in the following year totally routed the Ottoman army at Koniya, after which the porte ceded Syria to Mohammed 'Ali on condition of tribute. War breaking out again, the victory of Nisib in 1839 would perhaps have elevated him to the throne of Constantinople; but the quadruple alliance in 1840, the fall of St. Jean d'Acre to the British, and the consequent evacuation of Syria, compelled him to limit his ambition to the pashalik of Egypt. In 1848 Mohammed 'Ali became imbecile (he died in 1849), and his son Ibrahim sat on his throne for two months, when he died, and was succeeded by 'Abbās Pasha, Mohammed 'Ali's grandson, superseded in turn by Sa'id Pasha, youngest son of Mohammed 'Ali, in 1854. M. de Lesseps now obtained the co-operation, hitherto withheld, of the Egyptian government in his scheme of the Suez Canal, which was opened in 1869. Sa'id was succeeded in 1863 by his nephew, Isma'il, son of Ibrahim,

TOMB IN THE VALLEY OF EL ASSASSIF, THEBES, EGYPT

EGYPT

who, by a firman purchased from the Sultan, took in 1866 the hereditary title of Khedive. The same firman made the succession to the throne of Egypt direct from father to son, instead of descending, according to Turkish law, to the eldest male of the family; and in 1872 the Sultan granted to the Khedive the rights (withdrawn in 1879) of concluding treaties and of maintaining an army, and virtually gave him sovereign powers. Thus secure on an hereditary throne, Isma'il began a series of vast internal reforms, built roads, bridges, lighthouses, laid down railways, and telegraphs, reconstructed the postal service, improved the harbors at Suez, Port Sa'id, and Alexandria, supported education, and introduced mixed courts of law. Extending his dominions southward, he annexed Dar-Fur in 1874, and in that and the following year further conquests were made. The condition of the finances led to the establishment of "dual control" by Great Britain and France, and in 1879 Isma'il was forced to abdicate under pressure of the British and French governments, and was replaced by his son, Tewfik. His position was soon threatened by the so-called National party with Arabi Pasha at its head, who aimed at his deposition and at the abolition of European intervention. In May 1882, a rising took place in Alexandria, when many Europeans were killed and their houses pillaged. The Khedive fled from Cairo, where Arabi remained autocrat. The French refusing to interfere, Great Britain determined to act, and on 11 July a British fleet bombarded the forts at Alexandria, causing the rebels to retreat. In August a force under Sir Garnet (afterward Lord) Wolseley landed at Ismailia, and on 13 September Arabi's forces were totally defeated at Tel-el-Kebir, and the rebellion crushed, Arabi and his associates being banished. Before this a rebellion against Egyptian rule had broken out in the Sudan under the leadership of Mohammed Ahmed, who professed to be a Mahdi or divinely-sent Mohammedan conqueror. His followers soon became numerous, defeated Egyptian troops that opposed them, and threatened the existence of all the Egyptian garrisons in the Sudan. In 1883 they annihilated an Egyptian force under Hicks Pasha near El Obeid in Kordofan, and in 1884, Osman Digna, as representing the Mahdi, defeated another force under Baker Pasha near Suakim. British troops were now despatched to Suakim, and at El Teb and Tamai severe defeats were inflicted on the Arabs by Gen. Graham. Meantime Gen. Gordon had been sent to Khartum to withdraw the garrisons from the Sudan, but he was shut up in the town for nearly a year, and perished before the relief expedition under Sir Garnet Wolseley could reach him (January 1885). The Sudan was then given up, and the southern boundary of the Egyptian dominions fixed at Wady Halfa.

In 1892 Tewfik died, and was succeeded by his son, Abbas Hilmi, who is the seventh viceroy and third khedive of Egypt. In 1896 an Anglo-Egyptian expedition for the reconquest of the lost provinces was despatched under Sir Herbert (now Lord) Kitchener. Dongola was soon occupied. Abu Hamed was captured in the following year, and 8 April 1898, the insurgents were defeated in a battle near the confluence of the Atbara. Finally, on 2 Sept. 1898, the forces of the khalifa, as the Mahdi's successor was

called, were defeated with great slaughter at Omdurman, beside Khartum. The territory thus reconquered was placed under a governor-general, and was rapidly organized. A subsequent attempt of France to occupy Fashoda and enforce a claim to the Bahr-el-Ghazal valley led to some friction with Great Britain. See ALEXANDRIA; CAIRO; CLEOPATRA; EMIN PASHA; GORDON, GEN. C. G.; ISHMAILIS; KHEDIVE; MAHDI, MOHAMMEDANISM; MOSES; NAPOLEON; PHARAOH; PTOLEMY; SUDAN; SUEZ CANAL; TEWFIK; WADY HALFA.

Religion.—The ancient Egyptian religion was a philosophical pantheism, the various attributes of the Deity being divided among the different gods of the Pantheon. Unlike the Greek, where a god was honored in a separate temple, each Egyptian divinity was accompanied by a *put* or "company" of companion-gods. The principal nomes and cities had each a family group of gods, consisting of a parent deity, a wife and sister, and a son. Thus Ptah or Hephaestus, the eponymous and principal god of Memphis, formed a triad with the goddess Sekhet or Bast, and Imhotep; at Thebes the triad was Amen-ra, Mut, and Khons; and at Apollinopolis Magna, Har-bahut (Horus), Hathor, and Har-pakhrut (Harpocrates). These triads were usually, if not always, accompanied by inferior deities completing the *put*; and personifications of the elements, passions, and senses were introduced. The worship of some triads, however, became universal—that of Osiris, Isis, and Horus being found all over Egypt at the earliest period. The gods, indeed, are stated by the Greeks to have been divided into three or more orders or systems. The gods of the Memphite order were Ptah, Ra, Shu, Seb, Osiris, Set, or Typhon, and Horus; and Amen, Mentu, Atmu, Shu, Seb, Osiris, Set, Horus, and Sebak, according to the Theban system. Difficulties arise from the tendency to fuse different gods into one, particularly at a later period; Amen-ra, for example, being identified with Horus; and Horus, Ra, Khnum, Mentu, and Tum being merely considered the sun at different periods of his diurnal course.

A few foreign deities became at the close of the 18th dynasty engrafted into the religious system—as *Bar*, Baal; *Ashtarata*, Ashtaroth; *Anta*, Anaitis; *Ken*, Kiun; *Reshpu*, Reseph; *Set*, or Sutekh, sometimes identified with Baal. All the gods had human passions and affections, and their mode of action was material; they walked on earth, or sailed through ethereal space on boats. First among the deities comes Ptah, the opener, represented as a bow-legged dwarf or embryo, the Phœnician Pataikos, the creator of the world, the sun, and moon, out of chaos (*ha*) or matter, to whom belong Sekhet, "the lioness," and Bast, Bubastis, lion-headed goddesses presiding over fire, and Nefer-Tum, his son, a god wearing a lotus on his head. Next in the cosmic order is Khnum—worshipped at Elephantine—the ram-headed god of the liquid element, who also created the matter of which the gods were made; and connected with him are the goddesses Heka the Frog, or primeval formation, Sati, or "sunbeam," and Anuka, alluding to the genesis of the cosmos. The Theban triad comprised Amen-ra, "the hidden" power of the "sun," the Jupiter; *Mut*, the "Mother" goddess of "Matter," the Juno; *Nit*, the "Shuttle," the Minerva; and Khons,

EGYPT

"Force" or Hercules, a lunar type. A subordinate type of Ammon is Khem or Amsu, "the enshrined," who, as *Harnekht*, or Powerful Horus, unites beginning and end, or cause and effect.

A great variety of abstract principles and even animals and vegetables were, however, worshipped by the multitude, though the doctrine of one God was privately taught by the priests to a select few. To each deity an animal seems to have been held sacred, which was probably regarded as his symbolical representative. Bulls were consecrated to Osiris and cows to Athor; the sacred bull of Memphis, called Apis, being particularly venerated throughout Egypt. A hawk was the symbol of Re, the ibis of Thoth, the crocodile of Savak, and the cat of Phthah. Of the doctrines of the Egyptian religion little is accurately known. The existence of the spirit after death was believed, and a future state of rewards and punishments inculcated, in which the good dwelt with the gods, while the wicked were consigned to fiery torments amid perpetual darkness. It was believed that after the lapse of ages the spirit would return to the body, which was therefore carefully embalmed.

At the present day about nine tenths of the people in Egypt profess the Sunnite Mohammedan faith. About 750,000 are Christians and 25,000 are Hebrews. The Roman Catholics have two churches in Alexandria and two in Cairo. The Armenians also have a church and a bishop at Cairo. There is an American mission in both cities, but the natives are bigoted and exclusive and are not well disposed toward religious beliefs other than their own. See EMBALMING; MOHAMMEDANISM; IDOLATRY; PANTHEISM.

Literature.—See EGYPTIAN LITERATURE.

Ancient Architecture.—The monuments and traces of a past civilization found in Egypt are of two periods,—those built in the times of the Pharaohs, and those built during the sway of the Greek and Roman rulers of the country. Although the temples of the two periods differ considerably in plan and in other particulars, there is yet sound reason for believing that those built under the Greeks and Romans were constructed after designs, as they certainly occupy the sites of Pharaonic temples still more ancient than any now existing; that they were, in fact, mere restorations of temples built by the earlier Pharaohs.

The leading features of the now existing temples of the time of the Pharaohs are these: First, a gateway or pylon, flanked by two truncated pyramids. These occupy the entire width of the building, and form the entrance to a square court, surrounded by a portico supported by a double or single row of columns. Crossing this court the visitor passes through a second pylon into the inner court, which was likewise surrounded by a portico supported either by columns or by piers, against which were figures of the king. Beyond this second court it would appear the public were not admitted, for the spaces between the front row of columns or piers facing the gateway are occupied by a dwarf wall, which effectually barred entrance excepting at either one or three points where there were gates. This inner court led immediately into the largest chamber of the temple, called the Hall of Columns, the roof of which was

always supported by columns representing a grove of papyrus. The centre avenue was higher than the rest of the hall, and consisted usually of 12 columns, the capitals being imitated from the full-blown expanded papyrus, while the columns which sustained the lower roof were in the form of a bud of the same plant. To the Hall of Columns succeeded a series of smaller chambers, the roofs of which were generally supported by six or four columns, imitating the bud of the papyrus, either as a single plant or as several bound together; or else by square piers, or columns with 8, 12, or 16 faces. These apartments frequently surrounded a dark chamber—the most sacred in the temple—the holy of holies. Whether the roof of the portico which surrounded the court was supported by piers or columns, the structural arrangements were always precisely the same. There was first the pier or column, ordinarily made of several pieces of stone solidly united by mortar and wooden cramps; then came the architrave or frieze, of one block, stretching from column to column; and lastly, the blocks forming the cornice, concealing the ends of the roof stones which rested upon the architrave. The bulk of the column, in proportion to the weight it had to sustain, was extremely ample; and the pressure being always perpendicular, these ancient structures have come down to us with their roofs sound, while arched buildings of much less antiquity have been entirely ruined by the lateral pressure which that mode of construction exerts on the walls. The Egyptian gate was peculiarly simple. The lintel was always of one stone, and the door-posts also were very frequently of only one block, while each of the three portions had its appropriate decoration. Above the entrance was sculptured the winged globe or protecting divinity of entrances, with the names of the divinities to whom the temple was dedicated, and of the Pharaoh who built it. The door-posts also bore the name and title of the builder. The surface of each architectural feature was engraved with its particular ornament appropriately colored.

The temples built during the reigns of the Greek and Roman rulers may be thus described. First, the propylon, with its truncated pyramidal towers, which were sometimes adorned with narrow flags on tall poles; then a court surrounded on three sides with a colonnade. At the extremity of the court, and facing the gateway, was an elevated portico of six columns in line, and three or four deep. The uninitiated obviously were not permitted to enter beyond the court, for the columns of the first row of the portico are invariably joined by a dwarf wall, the only opening being between the centre intercolumniation, to which were attached the valves of the gate. To the portico succeeded a series of small chambers, the roofs of which were supported by four or by two columns. The centre chambers were lighted by small square openings in the roof, and those at the side by small openings in the walls; but in no example is there that kind of clerestory perforated with large openings, that occurs in the Hall of Columns of the Pharaonic temples. Besides the foregoing characteristics, there is an elaborate form of capital, representing the papyrus in three stages of growth, in one capital, or sometimes a collection of lotus flowers, or the full-blown papyrus alone; but in no instance do we find

EGYPT

the pier with the attached figure, nor the single bud of the papyrus, nor that form of column which represents several buds of the plant joined together. The palm-tree capital, however, belongs to both periods.

Among the most remarkable structures erected by the ancient Egyptians are the great pyramids, erected to serve both as monuments and as tombs. Strong buildings containing one or more rooms were also erected as tombs, in which food and other articles were deposited for the use of the dead, the inner walls being embellished with inscriptions and representations, and statues of the dead being also placed in the interior. Tombs cut in the rock were also common. In connection with architecture should be mentioned the obelisks, the oldest known being erected by Userthesen I. Sphinxes, often forming avenues, were a common accessory of temples, the greatest being that known as *the Sphinx*, a colossal companion of the pyramids of Gizeh. See ARCHITECTURE; OBELISK; PYRAMIDS; SPHINX.

Ancient Sculpture.—In portrait sculpture the Egyptians attained extraordinary perfection at an early date, the skill with which they worked in hard stone, such as diorite and basalt, being surprising. Some of the early statues are of colossal size, but a higher style of art is shown in those of ordinary size, though a certain conventional treatment is always apparent. The most usual kind of mural sculpture, a kind peculiar to the Egyptians, is that known as hollow or sunk relief (*cavo-rilievo*). The general outline of the object intended to be represented is cut into the smooth surface of the stone, while at the same time the minor forms and rotundity are represented within the incised outline. By this contrivance the details of the sculptures are protected. Sometimes the outline is excessively deep, at others the surface of the figures is altogether much lower than the general surface of the wall, and in others the outline is but slightly incised with a corresponding flatness within. Wherever the Egyptians practised the true bas-relief the sculpture is almost invariably in very low relief. The back view of the human figure is never represented in the sculptures excepting in the case of an enemy, and then rarely; the figure is generally represented in profile, and there are but few attempts at delineating the front view of the foot or of the face; however, whether the face be represented in front or side view, a profile eye is never found. The figures of the king in battle-pieces, and of the landed proprietor in domestic scenes, are always on a much larger scale than the other actors in the piece. Statues and reliefs were always painted, and when wall painting is employed it is always as a substitute for sculpture. There is no proper perspective, and certain conventionalities of color are employed. The Egyptians are represented with red and yellow complexions, red ochre for the men and yellow for the women. The hair of the king is frequently painted blue, but that of ordinary men black. In representing the various nations with whom Egypt had intercourse, the artists seem to have endeavored to imitate the complexions peculiar to each. Ammon-Re, the chief divinity of Thebes, is always painted blue, and he is further distinguished by two high feathers which he wears in his cap. The inferior divinities are not uncommonly of the complexions of mortals. The

sky or heavens are invariably indicated by a strip of blue coming downward at the lower side of each extremity, and occasionally having upon it a row of five-pointed stars. Water, seas, and rivers are represented by zigzag lines of a blue or green color. Mountains have a yellow color, with red spots upon it. Egyptian art was at its highest during the period between dynasties four and six, and notwithstanding its defects it was superior to that of Nineveh and Babylon. See ART; SCULPTURE.

Archæology.—The attention of the world was drawn to Egypt as a rich field for scientific exploration in the early part of the 19th century. In 1799, M. Boussard, one of Bonaparte's captains, found a large block of black granite in the trenches of Fort Julien near Rosetta; hence the name Rosetta Stone. On this were the remains of three inscriptions in hieroglyphic, demotic, and Greek characters. The stone was given to the British Museum by George III.

Emanuel de Rougé of France was the first to translate whole Egyptian books and inscriptions. His influence was felt in France by such men as Mariette, Chabas, Deveria, Pierret, Maspero, and by Revillout, the great demotic scholar of France, and by Birch, Hincks, Lepage, and Renouf in England. The practical archæologists of the German school, notably Lepsius, Bunsen, and Brugsch, translated the texts in the Egyptian temples in their relation to history and religion. Ebers used his scientific researches in novels. The German school has devoted itself more to grammars and philology, while the French school has made history and archæology its special study since Emanuel de Rougé's death. To Auguste Mariette (Mariette Pasha) is due the discovery of the Serapeum of Memphis. He cleared the temples of Edfu, Karnak, Denderah and Abydos. He explored the Nile valley from Tanis to Napata, and his collections of antiquities were moved in 1889 to Gizeh from Boulak. The museum there is famous. In 1896, Col. G. E. Raun discovered the cap of the Sphinx at Gizeh, which had been missing for centuries.

After Mariette the work of excavation was carried on by Maspero, Grebaut, and De Morgan, the first of whom resumed his post as director-general of antiquities in 1899. There is an archæological mission in Cairo, founded in 1880 by Maspero, who placed at its head successively Lefebvre, Grebaut, and Bouriant. Students go every year to Egypt to excavate. The Egyptian Research Account under Petrie trains students as explorers. The Egyptian Exploration Fund was founded in 1883 by Sir Erasmus Wilson, Prof. R. Stuart Poole, and Miss Amelia B. Edwards, and its American branch at the close of that year by the Rev. Dr. William C. Winslow of Boston, who had spent several months of archæological research in Egypt and attended at the removal of the obelisk in Alexandria for Central Park, New York. Edouard Naville of Geneva, was the first agent sent out. In 1883 he cleared the site of Pithom near the land of Goshen. The work of Naville, Griffith, Gardner, and Newberry resulted in important discoveries at Nauceatis, Tanis, Bubastis, Tal-paug, Ahnas, Denderah, Deir-el-Bahari, and Tel-el-Amarna. See EXPLORATION; NUMISMATICS, etc.

Recent Discoveries.—The last few years have seen wonderful discoveries in Egypt, for the tombs of the kings at Abydos have been opened

EGYPT

and the treasures which have been found place us face to face with the beginnings of history. Among the remarkable finds were a carved slate slab showing King Narmer smiting his enemy, an ebony table, a bar of gold, gold jewelry, including bracelets, and a royal sceptre. The oldest group of jewelry in the world is undoubtedly the four bracelets of the queen of King Zer (4715 B.C.), which was discovered with a portion of the mummy in a hole in a wall. This is 2,000 years earlier than any other jewelry thus far identified. The bracelets show a wonderful perfection in the soldering of the gold. The bracelets show the turning point in the development of Egyptian art, the finest bracelets being formed of alternate plaques of gold and turquoise, each surmounted with a royal hawk. The turquoise plaques have a more archaic and lumpy form of hawk than do the gold pieces, and show that during a comparatively short period, little more than half a century, rapid crystallization in art took place, and at the end of his reign the forms are practically identical with what continued for more than 4,000 years later. Dr. Flinders-Petrie considers that this is comparable to the sudden fixation of the final forms which is seen in Greek art, where an interval of only 40 years, between the time of the Persian war and the Parthenon, sufficed for the evolution from archaic work to the greatest perfection. Each of the royal tombs had two large tombstones, bearing the name of the king, and private tombs of all the court and domestics were placed around that of their royal master. They are nearly all built of brick, in most cases with a timber lining to the chamber sunk in the ground. They were originally roofed over with beams, matting and sand. They lie about a mile back from the Temple of Abydos and they were excavated by the Egyptian Exploration Fund.

An American archaeologist, Theodore M. Davies, has made one of the most interesting archaeological discoveries of recent years in excavating the tomb of one of the Pharaohs of the 18th dynasty, Thothmes IV. In this tomb was found the chariot in which Thothmes rode at Thebes. Like the other royal tombs Thothmes' tomb consists of a gallery cut in the heart of the mountain. After sloping downward for a considerable distance it is interrupted by a deep square well, on one of the walls of which is a band of paintings. On the farther side of the well the passage turns back, and finally opens into a large chamber, at the extreme end of which is a magnificent sarcophagus of granite covered with texts from 'The Book of the Dead.' On either side are smaller chambers, the floor of one of which was found to be covered with mummified loins of beef, legs of mutton, and trussed ducks and geese, offerings made to the dead king. Clay seals with the name of the Pharaoh had been attached to the doors of the chambers, and it is stated, these seals contain proof that the Egyptians of between 3,000 and 4,000 years ago had to some extent anticipated the invention of printing, the raised portions of the seals having been smeared with blue ink before being pressed on the clay. A great many of the objects in the tomb of Thothmes were found to be broken, and this was explained by a hieroglyphic inscription on one of the paintings which adorn the walls of the vestibule to the chamber in which the sarcophagus was found. This inscription states that the tomb was plun-

dered by robbers, but that it had been restored as far as possible to its original condition by Hor-em-heb, the reigning Pharaoh. The floor was covered with vases, dishes, symbols of life, and other objects of blue faience. Unfortunately, nearly all of them had been wantonly broken, though in some cases the breakage had been repaired in the time of Hor-em-heb. Equally interesting is a piece of textile fabric into which hieroglyphic characters of different colors have been woven with such wonderful skill as to present the appearance of painting on linen. It is, however, of course, the Pharaoh's chariot which is regarded as the great find. The body of it alone is preserved, but in a perfect condition. The wooden frame was first covered with papier mâché made from papyrus, and this again with stucco, which had been carved, both inside and out, into scenes from the battles fought by the Pharaoh in Syria. The art is of a very high order, every detail being exquisitely finished and the faces of the Syrians being clearly portraits taken from captives at Thebes. The chariot is, in fact, one of the finest specimens of art that have come down to us from antiquity. Along with the chariot was found the leather gauntlet with which the king protected his hand and wrist when using the bow or reins.

Recent excavations at Abydos have brought to light the royal tomb of Menes, of the first dynasty, in which was found a large globular vase of green glaze, with Menes' name inlaid in purple. Thus polychrome glazing is taken back thousands of years before it was previously known to exist. There are also several pieces of this age in the highest art of delicate ivory carving, especially the figure of an aged king, which, for subtlety of character, stands in the first rank of such work, and is comparable to the finest work of Greece and Italy. This fresh connection illustrates the trade chronology of the period. A camel's head modeled in pottery takes back its relation to Egypt some 4,000 years. Hitherto no trace of the camel appeared before Greek times. The ivory carving of a bear also extends the fauna of early Egypt.

Egyptian Bean, a name sometimes given to the bean-like fruits of the *Nelumbium speciosum*, or sacred lotus, found in China, India, Australia, but no longer on the Nile.

Egyptian Blue, a brilliant pigment consisting of the hydrated protoxide of copper mixed with a minute quantity of iron.

Egyptian Literature. The advance that has been made in recent years in the decipherment of the ancient writings of the world enables us to deal in a very matter-of-fact way with the Egyptian inscriptions. Their chief mysteries are solved, their philosophy is almost fathomed, their general nature is understood. The story they have to tell is seldom startling to the modern mind. The world was younger when they were written. The heart of man was given to devious ways then, as now and in the days of Solomon,—that we can affirm full well; but his mind was simpler; apart from knowledge of men and the conduct of affairs, the educated Egyptian had no more subtlety than a modern boy of 15, or an intelligent English rustic of a century ago.

To the Egyptologist by profession the inscriptions have a wonderful charm. The writing itself in its leading form is the most attractive that has ever been seen. Long rows of clever little pictures of things in heaven and earth compose the sentences; every sign is a plaything, every group a pretty puzzle, and at present, almost every phrase well understood brings a tiny addition to the sum of the world's knowledge. But these inscriptions, so rich in facts that concern the history of mankind and the progress of civilization, seldom possess any literary charm. If pretentious, as many of them are, they combine bald exaggeration with worn-out simile, in which ideas that may be poetical are heaped together in defiance of art. Such are the priestly laudations of the kings by whose favor the temples prospered. Take, for instance, the dating of a stela erected under Rameses II. on the route to the Nubian gold mines. It runs:—

On the fourth day of the first month of the season of winter, in the third year of the Majesty of Horus, the Strong Bull, beloved of the Goddess of Truth, lord of the vulture and of the uræus diadems, protecting Egypt and restraining the barbarians, the Golden Horus, rich in years, great in victories, King of Upper Egypt and King of Lower Egypt, *Mighty in Truth of Ra, Chosen of Ra*, the son of Ra, *Rameses Beloved of Amen*, granting life for ever and ever, beloved of Amen Ra lord of the "Throne of the Two Lands" in Apt Esut, appearing glorious on the throne of Horus

among the living from day to day even as his father Ra; the good god, lord of the South Land, Him of Edfu Horns bright of plumage, the beauteous sparrow-hawk of electrum that hath protected Egypt with his wing, making a shade for men, fortress of strength and of victory; he who came forth terrible from the womb to take to himself his strength, to extend his borders, to whose body color was given of the strength of Mentu; the god Horus and the god Set. There was exultation in heaven on the day of his birth; the gods said, "We have begotten him"; the goddesses said, "He came forth from us to rule the kingdom of Ra"; Amen spake, "I am he who hath made him, whereby I have set Truth in her place; the earth is established, heaven is well pleased, the gods are satisfied by reason of him." The Strong Bull against the vile Ethiopians, which uttereth his roaring against the land of the negroes while his hoofs trample the Troglodytes, his horn thrusteth at them; his spirit is mighty in Nubia and the terror of him reacheth to the land of the Kary; his name circulateth in all lands because of the victory which his arms have won; at his name gold cometh forth from the mountain as at the name of his father, the god Horus of the land of Baka; beloved is he in the Lands of the South even as Horus at Meama, the god of the Land of Buhen, King of Upper and Lower Egypt, *Mighty in Truth of Ra*, son of Ra, of his body, Lord of Diadems, *Rameses Beloved of Amen*, giving life for ever and ever like his father Ra, day by day. [Revised from the German translation of Professor Erman.]

As Prof. Erman has pointed out, the courtly scribe was most successful when taking his similes straight from nature, as in the following description, also of Rameses II.:—

A victorious lion putting forth its claws while roaring loudly and uttering its voice in the Valley of the Gazelles. . . . A jackal swift of foot seeking what it may find, going round the circuit of the land in one instant, . . . his mighty will seizeth on his enemies like a flame catching the ki-ki plant with the storm behind it, like the strong flame which hath tasted the fire, destroying, until everything that is in it becometh ashes; a storm howling terribly on the sea, its waves like mountains, none can enter it, every one that is in it is engulfed in Duat.

Here and there among the hieroglyphic inscriptions are found memorials of the dead, in which the praises of the deceased are neatly strung together and balanced like beads in a necklace, and passages occur of picturesque narrative worthy to rank as literature of the olden time. We may quote in this connection from the biographical epitaph of Ameny, who was governor of a province in middle Egypt for 25 years during the long reign of Usertesen I. (about 2716 B.C.). This inscription not only recounts the achievements of Ameny and the royal favor which was shown him, but also tells us in detail of the capacity, goodness, charm, discretion, and insight by which he attached to himself the love and respect of the whole court, and of the people over whom he ruled and for whose well-being he cared. Ameny says:—

I was a possessor of favor, abounding in love, a ruler who loved his city. Moreover I passed years as ruler in the Oryx nome. All the works of the house of the King came into my hand. Behold, the superintendent of the gangs of the domains of the herdsmen of the Oryx nome gave me 3,000 bulls of their draught stock. I was praised for it in the house of the King each year of stock-taking. I rendered all their works to the King's house: there were no arrears to me in any of his offices.

The entire Oryx nome served me in numerous attendances. There was not the daughter of a poor man that I wronged, nor a widow that I oppressed. There was not a farmer that I chastised, not a herdsman whom I drove away, not a foreman of five whose men I took away for the works. There was not a pauper around me, there was not a hungry man of my time. When there came years of famine, I arose and ploughed all the fields of the Oryx nome to its boundary south and north, giving life to its inhabitants, making its provisions. There was not a hungry man in it. I gave to the widow as to her that possessed a husband, and I favored not the elder above the younger in all that I gave. Thereafter great rises of

EGYPTIAN LITERATURE

the Nile took place, producing wheat and barley, and producing all things abundantly, but I did not exact the arrears of farming.

Elsewhere in his tomb there are long lists of the virtues of Amenemhat, and from these the following may be selected both on account of picturesqueness of expression and the appreciation of fine character which they display:—

Superintendent of all things which heaven gives and earth produces, overseer of horns, hoofs, feathers, and shells. . . . Master of the art of causing writing to speak. . . . Caressing of heart to all people, making to prosper the timid man, hospitable to all, escorting [travelers] up and down the river. . . . Knowing how to aid, arriving at time of need; free of planning evil, without greediness in his body, speaking words of truth. . . . Unique as a mighty hunter, the abode of the heart of the King. . . . Speaking the right when he judges between suitors, clear of speaking fraud, knowing how to proceed in the council of the elders, finding the knot in the skein. . . . Great of favors in the house of the King, contenting the heart on the day of making division, careful of his goings to his equals, gaining reverence on the day of weighing words, beloved of the officials of the palace.

The cursive forms of writing—hieratic from the earliest times, demotic in the latest—were those in which records were committed to papyrus. This material has preserved to us documents of every kind, from letters and ledgers to works of religion and philosophy. To these, again, "literature" is a term rarely to be applied; yet the tales and poetry occasionally met with on papyri are perhaps the most pleasing of all the productions of the Egyptian scribe.

It must be confessed that the knowledge of writing in Egypt led to a kind of primitive pedantry, and a taste for unnatural and to us childish formality; the free play and naïveté of the story-teller is too often choked, and the art of literary finish was little understood. Simplicity and truth to nature alone gave lasting charm, for though adornment was often attempted, their rude arts of literary embellishment were seldom otherwise than clumsily employed.

A word should be said about the strange condition in which most of the literary texts have come down to us. It is rarely that monumental inscriptions contain serious blunders of orthography; the peculiarities of late archaistic inscriptions which sometimes produce a kind of "dog Egyptian" can hardly be considered as blunders, for the scribe knew what meaning he intended to convey. But it is otherwise with copies of literary works on papyrus. Sometimes these were the productions of schoolboys copying from dictation as an exercise in the writing school, and the blank edges of these papyri are often decorated with essays at executing the more difficult signs. The master of the school would seem not to have cared what nonsense was produced by the misunderstanding of his dictation, so long as the signs were well formed. The composition of new works on the model of the old, and the accurate understanding of the ancient works, were taught in a very different school, and few indeed attained to skill in them. The boys turned out of the writing school would read and write a little; the clever ones would keep accounts, write letters, make out reports as clerks in the government service, and might ultimately acquire considerable proficiency in this kind of work. Apparently men of the official class sometimes amused themselves with puzzling over an ill written copy of some ancient tale, and with trying to copy portions of it.

The work, however, was beyond them; they were attracted by it, they revered the compilations of an elder age and those which were "written by the finger of Thoth himself"; but the science of language was unborn, and there was little or no systematic instruction given in the principles of the ancient grammar and vocabulary. Those who desired to attain eminence in scholarship after they had passed through the writing school had to go to Heliopolis, Hermopolis, or wherever the principal university of the time might be, and there sit at the feet of priestly professors; who we fancy were revered as demigods, and who in mysterious fashion and with niggardly hand imparted scraps of knowledge to their eager pupils. Those endowed with special talents might after almost lifelong study become proficient in the ancient language. Would that we might one day discover the hoard of rolls of such a copyist and writer!

There must have been a large class of hack-copyists practised in forming characters both uncial and cursive. Sometimes their copies of religious works are models of deft writing, the embellishments of artist and colorist being added to those of the calligrapher; the magnificent rolls of the 'Book of the Dead' in the British Museum and elsewhere are the admiration of all beholders. Such manuscripts satisfy the eye, and apparently neither the multitude in Egypt nor even the priestly royal undertakers questioned their efficacy in the tomb. Yet are they very apples of Sodom to the hieroglyphic scholar, fair without but ashes within. On comparing different copies of the same text, he sees in almost every line omissions, perversions, corruptions, until he turns away baffled and disgusted. Only here and there is the text practically certain, and even then there are probably grammatical blunders in every copy. Nor is it only in the later papyri that these blunders are met with. The hieroglyphic system of writing, especially in its cursive forms, lends itself very readily to perversion by ignorant and inattentive copyists; and even monumental inscriptions, so long as they are mere copies, are usually corrupted. The most ridiculous perversions of all date from the Ramesside epoch when the dim past had lost its charm, for the glories of the 18th dynasty were still fresh, while new impulses and foreign influence had broken down adherence to tradition and isolation.

In the 8th century B.C. the new and the old were definitely parted, to the advantage of each. On the one hand the transactions of ordinary life were more easily registered in the cursive demotic script, while on the other the sacred writings were more thoroughly investigated and brought into order by the priests. Hence, in spite of absurdities that had irremediably crept in, the archaistic texts copied in the 26th dynasty are more intelligible than the same class of work in the 19th and 20th dynasties.

In reading translations from Egyptian, it must be remembered that uncertainty still remains concerning the meanings of multitudes of words and phrases. Every year witnesses a great advance in accuracy of rendering; but the translation even of an easy text still requires here and there some close and careful guesswork to supply the connecting links of passages or words that are thoroughly understood, or the resort to some conventional rendering that has

become current for certain ill understood but frequently recurring phrases. The Egyptologist is now to a great extent himself aware whether the ground on which he is treading is firm or treacherous, and it seems desirable to make a rule of either giving the public only what can be warranted as sound translation, or else of warning them where accuracy is doubtful. A few years ago such a course would have curtailed the area for selection to a few of the simplest stories and historical inscriptions; but now we can range over almost the whole field of Egyptian writing, and gather from any part of it warranted samples to set before the reading public. The labor, however, involved in producing satisfactory translations for publication, not mere hasty readings which may give something of the sense, is very great; and at present few texts have been well rendered.

We may now sketch briefly the history of Egyptian literature, dealing with the subject in periods:

1. *The Ancient Kingdom, About 4400 B.C.—3000 B.C.*—The earliest historic period—from the First Dynasty to the Third, about 3766 B.C.—has left no inscriptions to any extent. Some portions of the 'Book of the Dead' (q.v.) profess to date from these or earlier times, and probably much of the religious literature is of extremely ancient origin. The first book of 'Proverbs' in the Prisse Papyrus is attributed by its writer to the end of the Third Dynasty (about 3766 B.C.). From the Fourth Dynasty to the end of the Sixth (3100 B.C.) the number of the inscriptions increases; tablets set up to the kings of the Fourth Dynasty in memory of warlike raids are found in the peninsula of Sinai, and funerary inscriptions abound. The pyramids raised at the end of the Fifth and during the Sixth Dynasties are found to contain interminable religious inscriptions, forming almost complete rituals for the deceased kings. Prof. Maspero, who has published these texts, states that they "contain much verbiage, many pious platitudes, many obscure allusions to the affairs of the other world, and among all this rubbish some passages full of movement and wild energy, in which poetical inspiration and religious emotion are still discernible through the veil of mythological expressions." Of the funerary and biographical inscriptions the most remarkable is that of Una, an official of King Mer-en-ra (Sixth Dynasty).

Another, later but hardly less important, is on the façade of the tomb of Hehrhuf, at Aswan, and recounts the expeditions into Ethiopia and the southern oasis which this resourceful man carried through successfully. In Hehrhuf's later life he delighted a boy king of Egypt by bringing back for him from one of his raids a grotesque dwarf dancer of exceptional skill; the young Pharaoh sent him a long letter on the subject, which was copied in full on the tomb as an addition to the other records there. It is to the Fifth Dynasty also that the second collection of 'Proverbs' in the Prisse Papyrus is dated. The Seventh and Eighth Dynasties have left us practically no records of any kind.

2. *The Middle Kingdom, 3000—1600 B.C.*—The Middle Kingdom from the Ninth to the Seventeenth Dynasty, shows a great literary development. Historical records of some length

are not uncommon. The funerary inscriptions descriptive of character and achievement are often remarkable.

Many papyri of this period have survived: the Prisse Papyrus of 'Proverbs,' a papyrus discovered by Mr. Flinders Petrie with the 'Hymn to Usertesen III.,' papyri at Berlin containing a dialogue between a man and his soul, the 'Story of Sanehat,' the 'Story of the Sekhti,' and a very remarkable fragment of another story; besides the 'Westcar Papyrus of Tales' and at St. Petersburg the 'Shipwrecked Sailor.' The productions of this period were copied in later times; the royal 'Teaching of Amenemhat' and the worldly 'Teaching of Dauf' as to the desirability of a scribe's career above any other trade or profession, exist only in late copies. Portions of the 'Book of the Dead' are found inscribed on tombs and sarcophagi.

3. *The New Kingdom, etc.*—From the New Kingdom, 1600—700 B.C., we have the 'Maxims of Any,' spoken to his son Khonsu Hetep, numerous hymns to the gods, including that of King Akhenaten (Amenhotep IV.) to the disk of the sun, and hymns to Amen Ra. Inscriptions of every kind, historical, mythological, and funereal abound. The historical inscription of Piankhi is of very late date. On papyri the stories of 'The Two Brothers,' of 'The Taking of Joppa,' and of the 'Doomed Prince.'

From the Saite period (Twenty-sixth Dynasty, 600 B.C.) and later, there is little worthy of record in hieroglyphics; the inscriptions follow ancient models. In demotic we have the 'Story of Setna,' a papyrus of moralities, a chronicle somewhat falsified, a harper's song, a philosophical dialogue between a cat and a jackal, and others.

Here we might end. Greek authors in Egypt were many; some were native, some of foreign birth or extraction, but they all belong to a different world from the ancient Egyptian. With the adaptation of the Greek alphabet to the spelling of the native dialects, Egyptian came again to the front in Coptic, the language of Christian Egypt. Coptic literature, if such it may be called, was almost entirely produced in Egyptian monasteries and intended for edification. Let us hope that it served its end in its day. To us the dull, extravagant, and fantastic 'Acts of the Saints,' of which its original works chiefly consist, are tedious and ridiculous except for the linguist or the church historian. They certainly display the adjustment of the ancient Egyptian mind to new conditions of life and belief; but the introduction of Christianity forms a fitting boundary to our sketch. See EGYPT; HIEROGLYPHICS.

SAMUEL AUGUSTUS BINION,

Author of 'Ancient Egypt or Mizraim.'

Egyptian Sudan. See SUDAN.

Egyptian Vulture (*Neophron percnopterus*), a well-known bird which frequents both shores of the Mediterranean, southern India, and, during the winter, south Africa. It is the scavenger of Egyptian villages, collecting in numbers where carrion or garbage is deposited, but feeding also on frogs, lizards, and small mammals found in cultivated fields. The birds usually go in pairs, however, and addict themselves to particular localities, being only drawn together in numbers by abundance of their favorite food. The name, as also that of Pharaoh's hen, is

given because of the frequent representation of this bird in Egyptian sculpture. See VULTURE.

Egyptology, the science of Egyptian antiquities. See EGYPT.

Ehninger, ā'n'ing-ér, **John Whetton**, American artist: b. New York 22 July 1827; d. Saratoga, N. Y., 22 Jan. 1889. He was graduated at Columbia College, studied two years under Comure in Paris and later at Düsseldorf, and served as staff-artist for an illustrated London journal. He was elected a National Academician in 1860. His works include landscape and figure subjects, among them being: 'Peter Stuyvesant' (1850); 'Eight illustrations of Miles Standish' (1858); 'Autumnal Landscape' (1867); 'Twilight from the Bridge of Pau, Basses-Pyrenees' (1878); 'Subject for Thanksgiving' (1879); 'Lady of the Manor' (1882); 'The Old, Old Story' (1884).

Ehrenberg, ā'rën-bërg, **Christian Gottfried**, German scientist: b. Delitzsch 19 April 1795; d. Berlin 27 June 1876. After studying theology, medicine, and natural history at Leipzig and Berlin, he joined in 1820 an expedition to Palestine, Egypt, and Abyssinia, returning to Berlin in 1825. In 1829 he accompanied Humboldt to the Ural and Altai ranges and to central Siberia. His great work on 'Infusoria' ('Die Infusionstierchen als vollkommene Organismen') appeared in 1838, and was at once recognized as the highest authority on the subject. It was followed in 1854 by his 'Microgeology.' Ehrenberg's work gave an enormous impetus to the study of microscopic organisms. He was the first to show that the phosphorescence of the sea is due to the presence of hosts of animalcules. Consult 'Life,' by Lane (1895).

Ehrle, Francis, German Catholic scholar: b. Isny, Württemberg, 17 Oct. 1845. He was educated at the Jesuit College, Munster, Westphalia, and after several years in mission work was transferred to Rome, where he devoted himself to historical studies. His 'History of the Church and its Literature in the Middle Ages' (in German) is based on extensive researches in the archives of Germany, England, Spain, and Italy. It is on this work that his reputation largely rests; but he has further written a Latin history of the Papal library from 1200 to 1417, and (with Stevenson) a history of the Vatican. He was made prefect of the Pontifical Library, and placed in charge of the Papal exhibit at the Louisiana Purchase Exposition, Saint Louis.

Eibenstock, i'bën-stök, Germany, town in the southeast of Saxony, near the Mulde, with important manufactures of lace. The tin mines nearby have been worked for about eight centuries. It is connected by rail with Chemnitz, about 40 miles distant. Pop. 7,500.

Eichberg, i'h'bërg, **Julius**, American composer: b. Düsseldorf, 13 June 1824; d. Boston, Mass., 19 Jan. 1893. After being professor in the Conservatoire at Geneva, he removed to New York in 1857, and in 1859 went to Boston, where he was director of the orchestra at the Boston Museum for seven years. In 1867 he established the Boston Conservatory of Music, of which he was at the head till his death. Four of his operettas are well known: 'The Doctor of Alcantara'; 'The Rose of Tyrol'; 'The Two Cadis'; and 'A Night in Rome.'

Eichendorff, i'hën-dórf, **Baron Joseph von**, German poet: b. Castle of Lubowitz, Silesia, 10 March 1788; d. Neisse 26 Nov. 1857. He was one of the most gifted and original romantic lyricists of Germany. His principal works are: 'Presage and Presence'; 'War to the Philistines,' a dramatic story; 'The Life of a Good-for-Nothing,' idealizing vagabondage; the tragedies 'Ezzelin von Romano,' 'The Last Hero of Marienburg'; and other plays, and a number of histories of German literature, including 'The Ethical and Religious Meaning of the New Romantic Poetry in Germany' (1847); 'German Romance of the Eighteenth Century in Relation to Christianity' (1851); 'History of German Poetry' (1857).

Eichens, Friedrich Eduard, frëd'rīn ed'oo-ärd i'hënz, German engraver: b. Berlin 27 May 1804; d. 5 May 1877. He studied in Berlin, Paris, and Parma, and returning to Berlin in 1832 was made a member of the Academy. He left many works, including: 'Vision of Ezekiel' after Raphael; 'Magdalen' after Dominichino; 'Christ in the Tomb' after H. Carrache; 'Prince Radziwill on His Deathbed' after M. Hanzel; and some engravings after Kaeilback.

Eichens, Philip Herman, German lithographer and engraver: b. Berlin 13 Sept. 1812; d. 1886. He was a brother of F. E. Eichens (q.v.). He studied under Henzel at the Berlin Academy, and among his engravings are: 'La Joconde'; and 'Return of the Pirates of Meyerkeim.' He received medals for his lithographs in Paris 1842, 1859, 1861, and 1863.

Eichhoff, Friedrich Gustav, frëd'rīn goos'täf i'h'höf, French philologist: b. Havre 17 Aug. 1799; d. Paris 10 May 1875. In 1842 he became professor of foreign languages at Lyons and in 1851 inspector-general of the University of Paris. He wrote a 'General Indo-European Grammar' (1867); etc.

Eichhorn, Johann Gottfried, yō'hän göt'frëd i'h'hörn, German theologian and Orientalist: b. Dörrenzimmern 16 Oct. 1752; d. Göttingen 25 June 1827. In 1775 he became professor of Oriental languages at Jena, and in 1788 at Göttingen. He edited a 'Repertory of Biblical and Oriental Literature' (1777-86); 'Universal Library of Biblical Literature' (1787-1803); and wrote 'Historico-Critical Introductions' to the Old and to the New Testament, and to the Apocryphal Books of the Old Testament; a 'Latin Commentary on the Apocalypse'; etc.

Eichrodt, Ludwig, lood'vīg, German poet: b. Durlach, Baden, 2 Feb. 1827; d. Lahr 2 Feb. 1892. He studied at Heidelberg and Freiburg and published in 1848 in 'Fliegende Blätter' his comic songs, 'Wanderlust,' which had great popularity. Among his works are: 'Poems of All Humors' (1855); 'Life and Love' (1856); 'The Chateau of the Voges' (1858); 'Hortus Deliciarum' (1875); 'Gold' (1880).

Eichstätt, i'h'stët, or **Eichstädt**, Middle Franconia, Bavaria, an old town in a deep valley of the Altmühl, 67 miles north-northwest of Munich. Its principal edifice is a fine Gothic cathedral, founded in 1259. Pop. 7,489.

Eider, a river of Prussia, in Schleswig-Holstein, which rises about 12 miles from Kiel, flows generally northwest, and after a course of 112 miles, of which 69 are navigable, empties into the North Sea at Tönning.

EIDER DUCK—EIGHT-HOUR DAY

Eider Duck, a bird of the sub-family *Fuliginæ*, or sea ducks, genus *Somateria*, distinguished by the peculiar form and feathering of the bill, and closely allied to the scoter ducks. The several species are confined to the northern regions. The American eider (*S. dresseri*) and the European eider (*S. mollissima*) are closely similar species which breed on solitary rocky shores and islands from Maine and the Farne Islands respectively, northward, the former species wintering as far south as the Delaware River. They are most abundant in Labrador, Newfoundland, Greenland, Iceland, and Norway, where they are stringently protected by law. Both species breed gregariously and in particular spots their nests are so abundant that a person can scarcely walk without treading on them. Their nests are usually formed of grass, dry sea-weed, etc., lined with a quantity of down which the female plucks from her own breast. In this soft bed she lays five eggs, which she covers over with a layer of down; then the natives, who watch her operations, take away both the eggs and the down, and this removal is repeated as often as she lays until the close of the season, when the last lot of eggs is allowed to hatch and the down removed from the nest only after the young have left. The drake does not, as is often stated, furnish any of the down. One female generally furnishes a few ounces of down. This down, from its superior warmth, lightness, and elasticity, is preferred by the luxurious to every other article for beds and coverlets; and, from the great demand for it, those districts in Norway, Greenland, and Iceland where these birds abound are regarded as the most valuable property and are guarded with the greatest vigilance. Proprietors endeavor to attract them by supplying artificial nests and otherwise, and when they settle in an island off shore, cattle and herdsmen are removed to allow them to breed undisturbed. The down from dead birds is little valued, having lost its elasticity.

The length of the eider duck is about 2 feet 3 inches, extent of the wings 3 feet, weight from 6 to 7 pounds; the head is large and the bill of singular structure, being 3 inches in length, forked at the base of the upper mandible in a remarkable manner, running high up on the forehead, and having the feathers on each side descending nearly to the nostrils; the whole of the bill is of a dull, yellowish horn color, somewhat dusky in the middle. The male is black beneath, head and back white, with a black crown. The female is reddish drab, spotted with black, with two white bands across the wings. Eiders associate in flocks, diving to great depths for shell-fish, which constitute their principal food. They live much on the water, retiring to the shores to rest, particularly on the appearance of an approaching storm. Their flesh is eaten, but tastes strongly of fish. The eggs, however, are esteemed. These and the down are both frequently obtained at the hazard of life by people let down by ropes from craggy steep.

Other species are the Pacific eider (*S. v-nigra*), and the remarkable king eider (*S. spectabilis*) of high Arctic regions. The now extinct Labrador duck (q.v.) is closely related.

Eidograph, ɪ'dō-graf, an instrument for copying designs invented by Prof. Wallace to re-

duce or enlarge them in any proportion, within certain limits; a form of pantograph.

Eidoscope, ɪ'dō-skōp, an instrument on the principle of the kaleidoscope, which produces an infinite variety of geometrical figures by the independent revolution of two perforated metallic disks. It may be employed with the magic lantern, when rapidly rotated, causing flashing rays of light, forming singular combinations to appear upon the screen. Various colored glass disks may be used, producing striking combinations of color.

Eifel, ɪ'fəl, **The**, a barren and bleak plateau of Rhenish Prussia, between the Rhine, Moselle, and Roer rivers, showing extensive traces of volcanic action. Its surface is diversified by crater-like depressions and volcanic peaks and ridges.

Eiffel, ā-fəl or ɪ'fəl, **Alexandre Gustave**, French engineer: b. Dijon 15 Dec. 1832. In 1858 he was intrusted with the construction of the large iron bridge over the Garonne at Bordeaux, and was one of the first to introduce caissons worked with compressed air. The bridge over the Douro at Oporto, the great viaduct of Garabit, in Cantal, and that over the Tardes, near Montluçon, and the gigantic locks designed and partly prepared for the Panama Canal are among later triumphs of his engineering skill; while in the huge framework erected for Bartholdi's 'Statue of Liberty' may be seen the germ of the idea which afterward assumed the form of the colossal iron structure (1887-9) on the Champs-de-Mars in Paris, with which his name is identified. See **EFFEL TOWER**.

Eiffel Tower, **The**, a notable structure in Paris. The plans for the exposition of 1889 included a monstrous iron tower, to be raised on the Champs-de-Mars, 1,000 feet high. The designer, Gustave Eiffel, constructed it of iron lattice-work, with three elevators giving access to the summit. The uses of so stupendous an undertaking are many, and it became one of the chief permanent ornaments of the city. Its importance from a meteorological point of view cannot be overestimated, the tower enabling meteorologists to study the decrease of temperature at different heights, to observe the variations of winds, and to find out the quantity of rain that falls at different heights, and the density of the clouds.

Eigenmann, ɪ'gen-mən, **Carl H.**, American zoologist: b. Flehingen, Germany, 1863. He was graduated at Indiana University in 1886 and studied at Harvard 1887-8. Between 1888 and 1892 he continued his scientific investigations in San Diego Biological Laboratory, the Woods Holl Marine Stations, and in the explorations undertaken for the British Museum in California, Oregon, Idaho, Montana, Dakota, and western Canada. He was appointed professor of zoology in Indiana University in 1891 and in 1895 founded and assumed the direction of the Biological Station of Indiana University. He has contributed more than a hundred papers to the proceedings of scientific societies and to scientific journals.

Eigg. See **Egg**.

Eight-hour Day. In the struggle for the shortest hours of labor compatible with the highest efficiency, begun in Great Britain early in the

EIGHT-HOUR LAW — EILETHYIA

19th century, the first great landmark was the Ten Hours' Bill of 1847, enforcing in all trades what had come about in many. But the golden ideal since 1824 (announced as such by Robert Owen in 1817) has been eight hours; possibly in remembrance that such was the rule in mediæval England; partly perhaps from the tempting threefold division of the day into equal parts, as in the rhyme "Eight hours for work, eight hours for play, eight hours for sleep, eight 'bob' a day." The eight-hour day was won in Australia in 1858. The movement on the Continent dates from the foundation of the "International" in 1864, and as a world-demand of the social reformers, from the Paris Trades-Union Congress of 1883. In the United States, till recently the subject was left to the States and to private contests, the government aiding by making short hours in its own works. In 1840 President Van Buren reduced the working day in the government navy yards to 10 hours. The first State 10-hour law, for textile workers only, was of 1849, in Pennsylvania. The first Massachusetts law was in 1874, and was due largely to the "Knights of St. Crispin." But the eight-hour movement had long before become general: in 1866 the demand was formulated at a general workingmen's congress at Baltimore, and at other meetings; and the National Labor Union was organized to secure an eight-hour day. A six weeks' strike in New England and New York, April-May 1866, attempted to secure it, but failed. In 1867 Connecticut and Illinois passed laws making eight hours a legal day "unless otherwise agreed." Pennsylvania followed in 1868 and New York in 1870. On 24 June 1869 the United States enacted an eight-hour day for its establishments; but the managers reduced wages correspondingly, allowing those who wished to work 10 hours at the old wages, which aroused such wrath that the President revoked the order. All these laws were rendered nugatory by the contracting-out clauses. In 1872 eight-hour leagues were formed in various places, and in Connecticut and New York a mass of strikes among the wood-working trades won this goal for a while; but the great depression from 1873 on prevented pressing such questions. Since 1880 several States have enacted the eight-hour law under the above conditions. But the first great concerted effort for eight hours was in 1886, when 200,000 workmen went on strike; it was at an eight-hour meeting in Haymarket Square, Chicago, that the anarchist bomb was thrown. A general strike was announced for this object in 1890, but was only partially successful, several hundred thousand workmen struck, and many employers yielded, but soon advanced the hours. The first really efficient national law was of 1 Aug. 1892, enforcing eight hours upon all laborers, mechanics, or contractors in the District of Columbia, under pain of fine and imprisonment. The short-hours' movement was first begun to protect women and children, the men sharing incidentally. It may be added that the practical results of the system are almost universally favorable. See Webb and Cox, 'The Eight-Hour Day' (1891); Rae, 'Eight Hours for Work' (1894).

Eight-hour Law, an act adopted in 1868 by the United States Congress, providing that in all government employment eight hours shall constitute a day's work. It originated in the

agitation which had begun in England in 1833 by the proposition of eight hours as a legitimate working day. The agitation spread itself among the industrial classes throughout the civilized world, and first bore fruit in Australia in 1856, where it was adopted by several trades. The National Labor Union of the United States demanded it in 1866, and it came into effect in the government navy yards in 1869, and shortly afterward in all departments of government work. Its universal adoption, however, is still unrealized, and it is the source of persistent agitation among the labor organizations and parties throughout the United States, the British Empire, and on the continent of Europe. Consult: Rae, 'Eight Hours for Work' (1894).

Eighth Nerve. See AUDITORY NERVE.

Eikon Basilike, *ī'kōn ba-sīl'ī-kē* (Gr. "the royal image"), a work the full title of which is *Εἰκὼν Βασιλική*: 'The Portraiture of His Sacred Majesty in His Solitudes and Sufferings.' It was published 9 Feb. 1649, 10 days after the execution of Charles I., and within 12 months ran through 50 editions in various languages. It professes to be Charles' own composition in the form of a diary. It is written in an affectedly dignified strain, and contains numerous assertions of love for his misguided and ungrateful people. At the Restoration, Gauden, afterward bishop of Worcester, laid claim to the authorship, and a memorandum in the copy of the Earl of Anglesea, lord privy-seal under Charles II., affirms that claim with the authority of Charles II. and the Duke of York. Milton's answer to it, 'Eikonoklastes' (that is "image-breaker") appeared the same year by order of Parliament. Gauden professed to have begun the work in or about the year 1647, and to have submitted a MS. copy of it to the king. On the other hand, those who maintain that the work was by Charles, assert that he had written the first six of its 28 chapters before the battle of Naseby (1645). The question is one of much complexity. Historians generally, from Lingard to Green, have pronounced against Charles; while some of those who have sifted his claims are in his favor. See GAUDEN, JOHN.

Bibliography.—Almack, 'Bibliography of the King's Book' (1896); Doble, in the 'Academy' (1883); Scott (E. J. L.) Comments in Edition of the 'Work' (1880); Wordsworth (Christopher), 'Who Wrote Icon Basilike?' (1824-5); 'King Charles I., the Author of Icon Basilike' (1828).

Eildon (*ēl'dōn*) Hills, three peaks belonging to a single mass, south of Melrose, in Roxburghshire, Scotland. The highest attains an elevation of 1,385 feet above sea-level, and all command a splendid prospect and are rich in historic and legendary associations.

Eilenburg, *ī'lēn-boorg*, Germany, town of Prussian Saxony, in the government of Merseburg, mainly situated on an island of the Mulde, 14 miles northwest of Leipsic. It has manufactures of calico, woolen cloth, and chemicals. Pop. (1900) 15,147.

Eilethy'ia (hieroglyph. *Nekheh*; city of Lucina, now called EL-KĀN), a city of ancient Egypt, situated on the right bank of the Nile, a little below Edfu. The present ruins consist of the remains of small temples dedicated by Ramesses III. to Ra; a Ptolemaic temple dedicated

to the eponymous goddess Lucina by Physcon or Euergetes II., with additions by Ptolemy Alexander I. and the elder Cleopatra; and an ancient temple dedicated by Amenophis III. to the local deities. The names of other monarchs are also found in the ruins; but the most interesting and important remains are the rock-tombs, some as early as the 13th dynasty, excavated in the hills. That of Aahmes, the "captain of the sailors," records his services in the wars of the early monarchs of the 18th dynasty against the Hyksos or Shepherds, and other Asiatic and Nigritic races. Another, that of Pahir, is decorated with rich and elaborate paintings, representing the pursuits of agriculture, fowling, fishing, etc. The city was an outpost against the southern tribes, and its fort, a large enclosure of crude brick, was of importance as early as the Shepherd war. The goddess Suben (Eilethia or Lucina) was a special protectress of Upper Egypt. Consult: Brugsch, 'Reiseberichte,' and 'Egypt Under the Pharaohs'; Wilkinson, 'Ancient Egyptians'; Mariette, 'Ancient Egyptian History.'

Eimbeck, im'bĕk, **William**, American geodesist: b. Brunswick, Germany, 29 Jan. 1841. He was for two years professor of mechanics and engineering, Washington University, and a member of the government solar eclipse expeditions to Illinois 1869 and to Italy 1870. He has been a Fellow of the American Association for the Advancement of Science since 1879, and is the inventor of the invariable reversible pendulum and the duplex base apparatus of coast and geodetic survey. His chief work has been in connection with the western divisions of the 39th parallel triangulation across the continent.

Eimeo, i'mĕ-ō, one of the Society Islands, in the Pacific Ocean, about 20 miles west-northwest of Tahiti, the principal member of the group; area 51 square miles. It consists of deep valleys and abrupt hills—the former well cultivated, and the latter heavily timbered. Here Christianity was first introduced in Polynesia; and here the South Sea College of the London Missionary Society was established. Most of the natives are Protestants. Pop. 1,500.

Einbeck, in'bĕk, or **Eimbeck**, Germany, town of Prussia, in the province of Hanover, on the Ilme, near its junction with the Leine, 40 miles south of Hanover. It carries on several industries, and the formerly celebrated Eimbecker bier ("bock" beer) is still made here. Einbeck was a place of importance in the 15th century. It was a member of the Smalkaldic League, and it figured prominently in the Thirty Years' and the Seven Years' wars. There are still remains of its old walls and towers. Pop. 8,436.

Einhard. See EGINHARD.

Einhorn, in'hörn, **David**, American rabbi: b. Dispeck, Bavaria, 10 Nov. 1809; d. New York 2 Nov. 1879. His first rabbinical position was at Hopstadten, Bavaria, and shortly afterward he became chief rabbi of the grand duchy of Mecklenburg-Schwerin. In 1851 he was called to Pesth, but his progressive tendencies aroused sharp opposition and his temple was closed by order of the government. In 1855 he was invited to become rabbi of the Har Sinai Congregation, of Baltimore, Md. His activity was now to be rapidly developed, for he issued his prayer-

book, which was warmly received by many reformed Jewish congregations, and he began the publication of a scholarly monthly magazine in German, entitled 'Sinai,' in the interests of advanced reform. His vigorous onslaughts on slavery in 1861 led to his removal from Baltimore to Philadelphia, there becoming rabbi of the Keneseth Israel Temple, and publishing his catechism. In 1866 he was elected rabbi of the Adath Teshurun Temple in New York, where he continued a zealous, impassioned and scholarly advocate of reform and the leader of the then radical school, until his retirement in July 1879.

Einsiedeln, in'zē dĕln (place of the solitaires or hermits), a small town in Switzerland, canton of Schwyz, seat of a renowned abbey of Benedictine monks since the middle of the 9th century. It is a famous resort of pilgrims who visit the place in thousands to venerate an ancient miraculous image of the Blessed Virgin. For the accommodation of the pilgrims the little town has more than 50 inns or houses of entertainment. Those pilgrimages are made throughout the year, but the great annual pilgrimage culminates on the anniversary of the dedication of the abbey's church, 14 September. The present abbey is the successor of four previous edifices which were destroyed by fire; it was erected in the first quarter of the 18th century, and is an imposing pile, in the Italian style. The place was visited by Edward Gibbon, the historian, 1755, who writes that he was "astonished by the profane ostentation of riches in the poorest corner of Europe; amidst a savage scene of woods and mountains a palace appears to have been erected by magic, and it was erected by the potent magic of religion." The abbey which Gibbon then saw is still in existence and is annually visited by more than 150,000 pilgrims. It was plundered of its vast treasure of silver and gold and precious stones by the French (1798), but it is still very rich, especially in literary monuments, possessing a library of 40,000 volumes, 1,190 manuscripts, and more than 1,000 productions of the printing press in its early period.

Eiselen, Wĭlhelm Bernard, vĭl'hĕlm bĕr'nārd i'zĕlĕn, German gymnast: b. Berlin 27 Sept. 1792; d. Misdroy, 22 Aug. 1846. His early studies began in Berlin, and he was the pupil of the eminent gymnast Jahns. He soon became prominent among the young gymnasts of Berlin, and in 1819 began to teach mathematics. He opened a fencing school in 1825 in Berlin and a gymnasium in 1828, and had a vast number of pupils. The first gymnasium for young girls was instituted by him in 1832. He published many works on gymnastics and fencing.

Eisenach, i'zĕ-nāh, Germany, town in the grand duchy of Saxe-Weimar, at the northwest end of the Thuringian Forest, at the confluence of the Nesse with the Hōrsel, 17 miles west of Gotha. In the market-place there is a monument to the memory of those from the neighborhood who fell in the war of 1870-1, and in the Karlsplatz stands the Luther memorial, unveiled in 1895. It contains many old buildings of historical and architectural importance. The manufactures are extensive, and comprise coloring materials, white-lead, woollens, beer, leather, pottery, tobacco, oil, machinery, etc. The town has many interesting historical associations. Luther

was at school here, and Sebastian Bach, to whom there is a statue, was born here. Near it is the Wartburg, where Luther resided for a time for safety. Eisenach was formerly the capital of a principality of the same name. Pop. (1900) 31,553.

Eisenberg, i'zën-bërg, Germany, a town in the province of Saxe-Altenburg, of great antiquity, birthplace of the philosopher Krause, whose statue is set up there. It possesses a famous castle, Christiansburg, and is the seat of many manufactures. Pop. (1895) 7,956.

Eisenerz, i'zën-ertz, Austria, a mining town of Austria, in the north of Styria, 20 miles northwest of Bruck. It stands in a narrow mountain valley at the foot of the Erzberg (5,000 feet), a mountain so rich in iron ore that the miners, instead of cutting mines into it and following the metal in veins, quarry the rock from the outside. Aragonite of the purest white, and resembling coral branches in form, is found in caves in the mountain. Pop. 7,000.

Eisenmenger, i'zën-mëng-ër, August, Austrian fresco painter: b. Vienna 11 Feb. 1830. He studied in the Vienna Academy, and early gained the first prize in drawing (1845). In 1863 he was appointed teacher of drawing in the Protestant Real-schule of Vienna. His first work of importance was the fresco which he executed in the hall of the Society of Musical Amateurs (*Musik Freunde*), 'Apollo with the Muses'; but he has painted many notable frescoes in other public buildings. He was appointed professor of the Vienna Academy in 1872, and at the same time opened a private school of fresco painting.

Eisleben, is'lā-bën, Germany, town in Prussian Saxony, 18 miles to the west of Halle, famous as the place where Martin Luther was born and died. The royal gymnasium, originally founded by Luther, was rebuilt in 1883. The house in which Luther died has been recently restored. In 1883, on the occasion of the celebration of the 400th anniversary of Luther's birth, a statue of him was unveiled in the market-place. Copper and silver are mined in the neighborhood of Eisleben. A considerable trade in flower and vegetable seeds is carried on. Pop. (1900) 23,900.

Eisteddfod, i-stet'h'vöd, the name of an assembly of Welsh bards for the purpose of musical and poetical contests. They were held at different places for the minstrels of their respective neighborhoods; at Caerwys, at Aberfraw in Anglesea, and at Mathravel in Powys. The judges were appointed by commissions from the native princes, and after the conquest from the English kings. The last was issued in 1568; but the ancient custom has been again revived by the Gwynnedigion and Cambrian societies, and annual meetings for the recitation of prize poems and performances on the harp are now held under the name of Eisteddfod. The Eisteddfod proper was announced a year and a day beforehand at an assembly called a gorsedd, at which prizes for the previous competition were awarded. At the present time yearly eisteddfods are held alternately in the north and south of Wales; and in some parts of the United States, especially throughout Pennsylvania, and other sections settled by the Welsh people, annual meetings take place, in every way similar

to the rite in their native land. During the Columbian Exposition at Chicago probably the most notable Eisteddfod held in this country, took place there.

Ejectment and Eviction. Ejectment in law is a mixed action, as it is resorted to in order to recover the possession of land, and damages for the wrongful withholding of it, though the damages are nominal. Originally, it was a possessory action—that is, adapted to the recovery of the possession of land. It ultimately became a convenient means of testing the title by a series of fictions. The supposition was (and this was the substance of the fiction) that a lease for a certain number of years had been made to a tenant, "John Doe," who had entered into possession, and had then been ejected by a person supposed to represent the party to be finally made defendant. This person was called "a casual ejector," and was usually represented as "Richard Roe." An action was then brought, substantially under the following title: "Doe, as tenant of Edwards (claiming the land), against Roe." A written notice was thereupon sent in the name of Roe by Edwards' attorney to the opposing claimant (Jones), who is the person in possession. By this notice Jones was advised to defend the action, otherwise Roe would permit judgment to be taken against him, and the possession would be lost. Jones, on making application to be made defendant, was allowed to defend on condition that he would admit the validity of the fictitious portion of these proceedings, so that the matter was narrowed down to a trial of the merits of the case. The action was now deemed to be between Edwards and Jones, although Doe still remained plaintiff on the records of the court. It was a rule in this action that the plaintiff can only recover upon a legal title, as distinguished from a title in a court of equity. He can succeed upon the strength of his own title, and of its validity, and not upon the weakness of that of his adversary. He must also have a right of entry. Where that does not exist another form of action must be resorted to. This method of procedure was defective in one particular. Any number of successive actions of ejectment could be brought by the plaintiff, although he had been defeated. The only check upon actions of this kind was a resort to a court of equity, for an injunction to prevent harrassing litigation. In England the fictitious portion of the proceeding was abolished by the Common Law Procedure Act of 1852, and the action placed upon satisfactory grounds. In New York and some other States the same result had been accomplished as early as 1830.

Eviction.—Depriving a person of his lands or tenements. Technically, the dispossession must be by judgment of law; if otherwise it is an *ouster*. Eviction may be total or partial. Total eviction takes place when the possessor is entirely deprived of his rights in the premises. Partial eviction takes place when the possessor is deprived of only a portion of them, as if a third person comes in and ejects him from a portion of his land, or establishes a right to some easement over it, by an older title than that under which he holds. See **DISPOSSESS**.

Ekaterinburg, ë-kä''të-rën-boorg', or **Iekaterinburg**, Russia, town, in the government and 170 miles southeast of Perm, on the east

side, and in the mining district of the Ural Mountains. It was founded in 1723 by Peter the Great. It has a mint, arsenal, custom-house, mining-school, hospital, and botanic garden. The art of cutting, polishing, and engraving gems, which are found in the neighboring mountains, is here carried to great perfection, and, together with mining and metallurgy, and a commerce in cattle and cutlery, forms the chief occupation of the inhabitants. Pop. 56,129.

Ekaterinodar, ě-kä''të-rë-nō-där', Russia, town, capital of the country of the Kuban Cossacks, on the Kuban River, about 100 miles from its mouth. It is surrounded on all sides by swamp and morass; it has a cathedral and a large military hospital, but its houses are mostly of earth, with low, thatched roofs. The three annual fairs are a means of increasing trade. Pop. 70,000.

Ekaterinoslav, ě-kä''të-rë-nō-slāv', or **Iekaterinoslav**, Russia, (1) town, capital of a government of the same name, on the right bank of the Dnieper, 250 miles northeast of Odessa. It was founded in 1787 by Prince Potemkin, as a summer residence for the Empress Catharine II. It has a cathedral, a public library; is the see of an archbishop, and the seat of several important public offices; and it carries on a large trade with Odessa. Pop. 121,216. (2) The government of the same name has an area of 26,148 square miles and a population of 2,112,651.

Ekhmim, ěkh-mēm', or **Ikhmim**, ěkh-mēm' (ancient APU or KHEMMIS, and called by the Greeks Panopolis), Egypt, town, on the east bank of the Nile near Suhāg; was formerly the capital of the ninth nome of the south country. Herodotus speaks of Khemmis as a large city with a temple dedicated to Perseus, and it was still a leading place of the Thebaid in the days of Strabo; but the Arab conquest demolished the greater part. It was once famous for linen manufacture and masonry, and is still noted for its check-cotton industry. Pop. 15,200.

Ekowe, Africa, the capital of the province of Zululand, in the colony of Natal, in South Africa.

Ek'ron, the northernmost of the five great cities of the Philistines (q.v.), on the borders of Judah and Dan. Beelzebub (q.v.) was its god. Akir, a railroad station on the road from Jaffa to Jerusalem is supposed to be on the site of what was once Ekron; and some of the old buildings are said to have been built in the times mentioned in the Old Testament.

El Bracito (N. M.), **Battle of** (Doniphan's name BRAZITO, Mexican TEMASCALITOS), 24 Dec. 1846, in the Mexican war. Col. Doniphan, marching from California to Chihuahua, was assailed at a bend of the Rio Grande, some 25 miles from El Paso, by a battalion of Mexicans under Antonio Ponce. The Mexicans fired at long range as they charged; the Americans waited till they came close, then broke them with a destructive volley, and a company of 20 horse scattered their cavalry, which fled to the mountains. American loss, 7 wounded; Mexican, 43 killed and 150 wounded.

El Caney, ěl-kä'nā, Cuba, town, on the main road, four miles northeast of Santiago de Cuba. During the Spanish-American war it

was the scene of a battle between 525 Spaniards under Gen. Vara del Ray, and 4,400 Americans under Gen. Lawton. The Spaniards lost 320, and 100 were taken prisoners; the Americans lost 440. This battle occurred 1 July 1898. In 1901 the United States government purchased the battlefield and approaches for a public reservation. See SPANISH-AMERICAN WAR.

El Dorado. See ELDORADO.

El Dorado, Kan., city, county-seat of Butler County; on the Walnut River; the Atchison, T. & S. F., and the Missouri P. R.R.'s; about 25 miles east of Wichita. The city is situated in a rich agricultural region, and its principal trade is in dairy and farm products. There are several manufacturing plants, and a limestone quarry. Pop. (1900) 3,466.

El Fasher, ěl fā'shër, Sudan, (1) Capital of Darfur in the Egyptian Sudan. It lies at the foot of the eastern slope of the Jebel Wanda, and there is an important trade-route connecting it with Dongola on the Nile. (2) Another town of the same name stands on the river Atbara, near the Abyssinian frontier.

El Hasa, ěl-hā'za, a fertile district of eastern Arabia, on the Persian Gulf, belonging to Turkey. It produces dates, wheat, millet, rice, etc. Area, 31,000 square miles. It contains the towns of El Katif, El Hofuf, and Koweit. Pop. about 160,000.

El-Khargeh. See KHARGEH, EL.

El Obeid. See OBEID, EL.

El Paso, ěl pā'sō, Texas, city, port of entry, county-seat of El Paso; on the Rio G.; the Atchison, T. & S. F.; the Texas & P.; the Rock I., and El Paso & N. R.R.'s; 712 miles northwest of Austin. The pass, El Paso del Norte, the principal thoroughfare between Mexico and New Mexico through the mountains, is near the city, which is a customs port. It is opposite Ciudad Juarez, the north terminus of the Mexican Central Railroad in Mexico, across the Rio Grande. El Paso has a Federal building, costing \$200,000, the Rio Grande Congregational Training School, three national banks, and various manufactories, and carries on an extensive grain trade. The smelting establishments are remarkable, especially that of the new oil-burning blast-furnace plant of the American Smelting & Refining Company, which occupies nine acres with its closely packed buildings. It is the first establishment of the kind to use successfully oil as a power generator. The capacity of the plant which may be indefinitely expanded, is 40,000 tons of ore per month, and all ores can be treated except zinc running over 15 per cent metal. Beaumont oil for fuel is kept in an underground tank of 75,000 gallons capacity. The ores are shipped in large quantities from New Mexico and Mexico. It is a noted health resort for victims of lung trouble. In the calendar year 1900, the imports of merchandise aggregated \$1,280,985; exports, \$5,482,323; imports of gold and silver, \$12,036,602. Pop. (1900) 15,906.

Elæagnus, ěl-ē-ag'nūs, a genus of shrubs or small trees of the natural order *Elæagnaceæ*. The species, of which there are about 15, are natives of the northern temperate zone, and are characterized by deciduous, entire leaves covered

with silvery or brownish scales, solitary or clustered apetalous axillary flowers, and one-seeded drupaceous fruits. They are valued in ornamental gardening for their foliage, usually decorative fruits and mostly fragrant flowers. The deciduous members are hardy in the north; the evergreen ones, which mostly come from Japan and China, only in the south. They are easily propagated by means of seeds, cuttings, and layers, and succeed upon almost any well-drained soil in a sunny situation. The best known species probably are: (1) *E. angustifolia*, the oleaster, or white olive, which attains a height of about 20 feet. It has been introduced from southeastern Europe or adjacent Asia, and has proved hardy in the bleak and cold prairie States. It is one of the most ornamental species. (2) *E. argentea*, the silver-berry, a native of the colder parts of Canada and the northern border of the United States. It seldom attains a height exceeding 15 feet and is perhaps the most popular native species. (3) *E. longipes*, the goudi, a species introduced from eastern Asia. It is gaining in favor. It attains a height of about six feet and, like the preceding, bears edible, slightly acid fruit of pleasant flavor. This last species became of horticultural importance during the last 25 years of the 19th century because it produces good crops of fruit in climates too rigorous for most of the other fruit-bearing shrubs and trees.

Elæis, ě-lē'is, or **Elais**, the name given to a genus of palms, tribe *Cococa*, and the spiny section of that tribe. It is dioecious or monoecious; the flowers, especially the males, in dense masses, packed very closely together; the fruit is partly three-sided, but somewhat irregular. *E. guineensis*, the maba or oil-palm of the West African coast, has heads of large fruits. The outer or fleshy part of the fruit is boiled in water, when the oil rises to the surface and may be skimmed off. In its native country it is used for butter. It constitutes one of the chief commercial products of western Africa. *E. melanococca* also furnishes oil. Both species yield by manufacture palm-wine.

Elæocarpacæ, ě-lē-ō-kār-pā'ce-ē, a sub-order of *Tiliacæ*, mostly East Indian trees. The fruits of some are eaten. The deeply wrinkled seeds or stones of the fruit of *Elæocarpus ganitrus* are made into beads for necklaces and bracelets in India. They are often called olive nuts.

Elæocarpus, ě-lē-ō-kār'pūs, a genus of plants of the linden family (*Tiliacæ*), to which belongs the American basswood. The species of the genus are shrubs and trees, and are found chiefly in New Zealand, Australia, and southeastern Asia. The plants are of commercial importance wherever they grow. From the seed-stones of *E. ganitrus* the natives of Australia make necklaces. The New Zealanders find a rich black dye in *E. lunau*, and in India several species furnish one of the ingredients of curry-powder.

Elæococca, ě-lē-ō-kōk'a, a genus of the spurge family (*Euphorbiacæ*). The pressed seeds of *E. verrucosa*, a Japanese plant, furnish oil for burning, as do those of the Chinese *E. vernicia* oil for mixing with paint. Both these plants are cultivated and are now known under the common name of *Aleurites cordata*.

Elæodendron, ě-lē-ō-dēn'drōn, a genus of the staff-tree family (*Celastracæ*). The plants of the genus are generally trees, natives of Ceylon, southern Asia, and western and southern Africa. The drupes of *E. kumbu* are eaten at the Cape of Good Hope, while the bark of *E. roxburghii*, rubbed with water, is used by the Hindus as an external application to swellings of all kinds. *E. glaucum*, a native of Ceylon, is sometimes called the Ceylon tea-tree. Saffronwood is the product of *E. croceum*, and an oil in common use in Africa is made from *E. argan*.

Elagabalus, ě-la-gāb'a-lūs, or **Heliogabalus**, hē'li-ō-gāb'a-lūs, Roman emperor: b. Emesa 204 A.D.; d. 222. His real name was Varius Avitus Bassianus, but having, when a mere child, been appointed high-priest of the Syro-Phœnician sun-god Elagabol, he assumed the name of that deity. Soon after the death of his cousin, Caracalla, Elagabalus was proclaimed emperor by the soldiers, in opposition to the legitimate sovereign, Macrinus. The rivals met in battle at Antioch 218 A.D., Macrinus was defeated, and Elagabalus assumed the purple. His reign of three years and nine months was infamous for the debaucheries of every kind in which he indulged. He instituted ceremonies in honor of the god Elagabol, and it is believed made human sacrifices to him. He was murdered in an insurrection of the Prætorians and was succeeded by his son, Alexander Severus.

Elaine, ě-lā'in, or **Elain**, a name for the oily principle of fat obtained by submitting fat to the action of boiling alcohol, allowing the stearin to crystallize, and then evaporating the alcoholic solution; or by the simple process of pressing any oily or fatty substance between folds of bibulous paper, the oily matter or elaine is absorbed, while the stearin remains. The paper being then soaked in water and pressed, yields up the elaine. It possesses much the appearance and properties of vegetable oil, is liquid at the temperature of 60° F., and has an odor derived from the solid fats from which it has been extracted.

E'lam, the ancient name of a country or region in Asia, east of the Lower Tigris. The cuneiform inscriptions record that a king of Elam conquered Babylonia and Assyria about 2300 B.C. The later ancient writers call this country Susiana, the name being derived from its capital, Susa or Shushan, one of the most ancient cities of the East. It is now known as Khoozistan. Both the country itself, which seems to have been of considerable importance at an early period, and its capital, Shushan, are mentioned in the Bible.

Consult: Sayce, 'Inscriptions of Mal Amir'; Loftus, 'Travels and Researches in Chaldæa and Susiana'; Billerbach, 'Susa'; Dieulafoy, 'L'Acropole de Suse.'

Eland, ē'land, the largest antelope (*Oreas canna*) found in Africa. It is as big as a fully grown horse, weighs 1,000 pounds or more, and stands fully six feet high. The early settlers in South Africa called it "elk." The eland has a short, smooth coat of rich fawn color; strong, straight horns about 20 inches long; and a broad fringed dewlap falling about to the knees. The hide makes excellent harness

ELANET — ELASTICITY

leather; and the flesh is decidedly palatable. The elands move so slowly, and are such gentle creatures, as to be easily caught, and hence have been nearly exterminated in their native haunts. At present very few are found. In the equatorial region of western Africa is found the still larger species (*Oreas derbianus*).

Elanet, ɛl'a-nět, *Elanus*, a genus of *Falconidae*, allied to the kites, which they resemble in many of their characters; but from which they differ in having the short tarsi half covered with feathers, and the claws, except that of the middle toe, rounded beneath. The tail is very little forked. One species (*E. melanopterus*) is common in Africa from Egypt to the Cape of Good Hope, and is found also in India. Another species is the black-shouldered hawk (*E. dispar*) of America, the northern limit of which appears to be South Carolina. Both of these feed chiefly on insects, which they catch on the wing, but they also prey on small birds and reptiles.

Elapidae, ɛ-läp'i-dē, or **Elapinae**, a group of highly venomous snakes, having a short, rounded head covered with plates. They are more nearly related to the harmless colubrids than to the vipers, but have a poison apparatus of the proteroglyph type, which are smaller than in the viperine snakes, but very deadly. The group is a large one and found in most parts of the world, but is most numerous in the tropics. Nearly all the snakes of Australia are elapine, the whole race of cobras (q.v.), the coral and harlequin snakes and others. The genus *Elaps* is entirely American, and is represented by a single species in the United States (Florida).

Elaps, ɛ laps. See CORAL-SNAKE.

Elasmobranchii, ɛ-läs-mō-bräng'k'i-i, a subclass of fishes, containing the sharks and rays. The skull is cartilaginous with only superficial calcifications and no true dermal bones; the gills fixed and shaped like pouches; the upper jaw is the pterygo-palatine bar, and the lower jaw Meckel's cartilage, attached to the skull by a large hyo-mandibular element; the exoskeleton consists of tooth-like granular tubercles or spines; and the trunk endoskeleton is cartilaginous. The ventral fins are far back and bear claspers in the males; the heart has but one auricle and one ventricle; and the intestine is provided with a spiral valve. The group is nearly coextensive with Cuvier's *Chondropterygia* or cartilaginous fishes and the Placoidi of Agassiz, and has received various other names such as *Selachii* and *Plagiostomi*. Cope distinguishes as orders the *Selachii*, which includes all living as well as many extinct forms; and the *Ichthyotomi*, which are exclusively carboniferous and have simple claspers and extensive cranial calcifications. See DOGFISH, RAY, SAWFISH, SHARK, SKATE, etc.

Elasmosaurians, ɛ-läs-mō-sä'ri-anz, gigantic marine fossil reptiles of the order *Sauropterygia*, found in cretaceous beds. As a living animal it was contemporaneous with *Plesiosaurus*, of the same order, which abounded in the eastern hemisphere, and as a fossil has been found in Europe and New Zealand. *Elasmosaurus* had a lizard-like, elongated body, sometimes 45 feet long, flattened limbs which served as oars, and a long, paddle-shaped tail which assisted its motion through the water. The head

was proportionately small, and with the neck performed twisting motions much like the corresponding parts of the swan. The contents discovered in the body indicate that this seasaurian lived on other rapacious fish, which it was able to seize with its crocodile-teeth. The fossil has been raised from cretaceous beds in New Jersey and in Kansas.

Elasmotherium, ɛ-läs-mō-thē'r'i-um, an extinct rhinoceros which inhabited Siberia and Russia during the Pleistocene Epoch. It exceeded the Indian rhinoceros in size, and bore an enormous horn on the frontal bone of the skull. The teeth are very long-crowned, with the enamel ridges strongly crenulated. Some of the native Siberian legends are supposed to refer to this animal; it was a contemporary of early man in that region.

Elastic Limit. See ELASTICITY.

Elastic Tissue, fibrous tissue in most cases mixed with the fibres of areolar tissue. It occurs in the ligaments of the vertebrae, that of the jaw, etc., also in connection with arteries, veins, and lymphatics. It is used in the animal structure whenever an extensible and highly elastic material is required.

Elasticity, that property of bodies in virtue of which they tend to return to their original shape or bulk, after having been subjected to distortion, compression, or extension. The fundamental principles of the theory of elasticity are well understood; but in applying these principles to the precise solution of the practical

FIG. 1.

FIG. 2.

problems that arise in physics and engineering, mathematical difficulties are encountered which often appear to be insuperable. In fact, there are comparatively few problems in elasticity whose solutions are known with precision, except in those cases in which the deformation of the body under consideration is exceedingly small. In the study of such problems we have to deal (1) with the deformation that the elastic body experiences, and (2) with the forces that are associated with that deformation. In the convenient phraseology of Rankine (which has been generally adopted by later writers), the deformation itself is called a "strain," and the internal forces that the continued existence of this strain implies are collectively known as the "stress." Rankine's own language on this point is as follows, save for a single minor modification: "The word 'strain' will be used to denote the change of volume and figure constituting the deviation of a definite elementary portion of a solid from that condition which it preserves when free from the action of external forces; and the word 'stress' will be used to denote the force, or combination of forces, which this same elementary portion exerts in tending to recover its free condition, and which, for a state of equi-

ELASTICITY

librium, is equal and opposite to the combination of external forces applied to it." These definitions being established, the theory of elasticity may be defined as that branch of pure mechanics which deals with the stresses and strains to which elastic bodies are subject. In an æolotropic or anisotropic body, such as a crystal belonging to the orthorhombic, monoclinic, or triclinic system (see CRYSTAL), the elastic properties are different in different directions, and it is found that the equations that are required in order completely to specify the connection between the stresses and strains that may exist in such a body involve no less than 21 constants.

FIG. 3.

FIG. 4.

It is easy to understand that this fact implies enormous mathematical difficulties in the solution of problems relating to such bodies; and these intrinsic difficulties are still further enhanced by the fact that there is probably not one substance in nature, for which the actual numerical values of these constants are all known. (For a thorough but necessarily difficult discussion of the elastic theory of crystalline bodies, consult Rankine's 'Axes of Elasticity and Crystalline Forms,' in his 'Miscellaneous Scientific Papers.') When, on the other hand, the body has exactly the same properties in all directions (or is "isotropic"), it is found that only two constants are required; but even in this comparatively simple case the mathematical difficulties of the general theory are so great that it is usually impossible to solve problems in which the deformations to be considered are of any considerable magnitude.

In the remaining portion of this article it will be assumed that the body under consideration is strictly isotropic—that is, that it has the same

FIG. 5.

elastic properties in all directions, and in all its parts. Fortunately this restriction is not incompatible with the great majority of problems that arise in practical work. In such a body, as has been said above, there are but two independent elastic constants, which have to be determined by experiment for the particular substance under consideration. These are known, respectively, as the "bulk modulus" (or "volume modulus"), and the "modulus of simple rigidity," though numerous other names are also applied to them. If V is the original volume of an isotropic solid, and $V - v$ is its volume when

subjected to a uniform normal pressure of P pounds per square inch over its entire surface, then $\frac{v}{V}$ is called the "compression," and the "bulk modulus" of the body (which is commonly represented by the letter k) is defined as

$$k = P \div \left(\frac{v}{V} \right) = P \left(\frac{V}{v} \right)$$

The values of this modulus for some few common substances are given below.

The modulus of simple rigidity is usually defined by reference to the distortion that a small cubical portion of the unstrained solid undergoes when the distorting force is applied. Fig. 1 represents a cube of this sort, which is supposed to be so small that the force acting upon any one of its faces may be considered to be uniform over the entire face. When such a cube is in equilibrium the most general kind of stress to which it can be subjected is resolvable into stresses of two types: (1) a uniform compressive stress, acting with equal intensity on all its faces, and therefore tending merely to alter its volume without producing any distortion of form; and (2) four equal forces, acting upon four of the faces, and disposed in pairs as shown in Fig. 1, one pair being directed inward and the other pair outward. The system of forces shown in Fig. 1 tends to alter the shape of the cube by extending it in one direction, and flattening it in a direction at right angles thereto; but there is no tendency in such a system to alter the bulk of the cube, since the extension produced by one of the pairs of forces is exactly neutralized by the compression produced by the other pair. If the dotted line in Fig. 1 were a line of weakness across the cube, it is evident that the effect of the force-system in that figure would be to cause the upper part of the cube to slip, relatively to the lower part, as suggested in Fig. 2. In fact, if the forces acting upon the upper part are compounded together, and those acting upon the lower part are also compounded in the same manner, it is plain that the four forces of Fig. 1 may be considered to be equivalent to the two that are shown in Fig. 3; so that the tendency of the stress-system shown in Fig. 1 is merely to cause one part of the cube to slide, relatively to the other part, along a plane that is parallel to the direction in which the resultant forces act. A stress such as is here described is called a "shear." To estimate the resistance of a body to deformation by the action of a shearing stress, consider a small cube to be cut from the original one, as suggested by the dotted lines in Fig. 4; and for the sake of fixing the ideas, let strips be conceived to be cemented to this cube at the top and bottom, as indicated in Fig. 5, so that the equal and opposite distorting forces can be conveniently applied. Then the effect of the forces in Fig. 5 will be to distort the cube into the shape indicated by the oblique dotted lines, and the magnitude of the angle i may be taken as the measure of the rigidity of the material of which the cube is composed; this angle being smaller (for a given shearing stress), the greater the rigidity of the substance considered. Stresses such as those shown in Fig. 5 are said to be "tangential"; and the "modulus of rigidity" of a substance may be obtained experimentally by applying such a pair of tangential

ELASTICITY

forces to a unit cube of the substance, and then dividing either of these equal and opposite tangential forces by the observed value of the angle α , as expressed in radians. The modulus of rigidity is commonly denoted by the letter n .

The bulk modulus and the modulus of rigidity of an isotropic substance being known, problems concerning the elastic behavior of that substance can be solved by known mathematical methods, when the strains to be considered are quite small. For these methods, advanced treatises on theoretical mechanics must be consulted. One of the best books, so far as the presentation of the general principles of the subject is concerned, is that of H. Poincaré, (*Leçons sur la théorie de l'élasticité*.)

Different bodies possess different degrees of elasticity, both of bulk and of form, and the elasticity of the same body will usually vary sensibly with the temperature. A body in which a certain definite strain is always accompanied by identically the same condition of stress, at a given temperature, without regard to the variations of temperature, bulk, and form to which it may have been subjected in the intervals between successive repetitions of the experiment, is said to be "perfectly elastic." Fluids (that is, gases and liquids) possess perfect elasticity of bulk, since a given fluid always requires the application of the same pressure, in order that its bulk may be diminished by a given constant amount, at a fixed temperature. Many solids also appear to possess perfect elasticity, both of bulk and of form, so long as the strains to which they are subjected do not exceed certain limiting values. Thus when a bar of steel is extended by the application of a longitudinal tension, it will return to its original length when the tension is removed, provided the extension that was produced (when expressed as a fraction of the total length of the bar) did not exceed a certain limit. If the extension exceeded this limit, the bar will shorten upon the removal of the tensile force, but will not return precisely to its original length. The permanent elongation so produced is technically known as the "permanent set" of the material. The tensile force that will just extend a bar of unit sectional area to the point at which it first receives a permanent set, is often called, commercially, the "elastic limit" of the material; though the expression "yield point," which is less generally employed, appears to be preferable. When a tensile force is applied to such a bar as we have been considering, and in such a manner that the force, at first zero, increases gradually up to a maximum value, the bar stretches under its influence, and it is observed that for a considerable time the extension of the bar is almost precisely proportional, at any given instant, to the force that is being exerted at that instant. As the bar approaches its yield point, however, the extension is found to exceed the value that it would have if the law of proportionality held good up to the yield point. The tensile force to which a bar of unit sectional area is subjected when the departure of the extension from strict proportionality to the force is first observed is also often called the "elastic limit" of the material; though, since it does not coincide with the yield point, it is more accurately described as the "limit of proportionality." The general phenomena here discussed are observed also in connection with strains other than

mere extensions. Thus when solid bodies are deformed in any way by the application of an external force, a permanent set is observed if the deforming force is large enough; and the deformation, which at the outset is proportional to the applied force, ceases to be so when that force attains to a certain limiting value. In some cases, however, fracture of the material may supervene before any permanent residual set can be actually realized, and the deformation of the material may also remain sensibly proportional to the applied force, even up to the point of fracture. The general law that the distortion of an elastic body is strictly proportional to the applied force, provided that force does not exceed a certain limit, is known as "Hooke's law," from the fact that it was first explicitly stated by Robert Hooke, for the simple case of the extension of a bar by tension (*Ut tensio sicut vis*).

When a straight bar of metal (or other solid substance) is subjected to an endwise pull, it elongates in the direction of the tension, and contracts in all directions at right angles thereto. If L is the original length of the unstrained bar, and $L + l$ is its length when sub-

jected to the longitudinal tension P , the ratio $\frac{l}{L}$

is called the "longitudinal extension" of the bar, under the influence of the tension P . From Hooke's law it follows that the longitudinal extension, as so defined, is proportional (for small strains) to the force P , so that the quotient obtained by dividing the force P by the longitudinal extension that it produces is constant. When the sectional area of the bar is unity (or, what amounts to the same thing, when P is the tension per unit of sectional area of the bar),

this constant, which has the value $\frac{PL}{l}$, and is

usually denoted by the letter E , is called "Young's modulus," from the fact that its importance was first recognized by Dr. Thomas Young. Since the elastic properties of an isotropic body are determinate when the "bulk modulus," k , and "modulus of rigidity," n , are known, it follows the Young's modulus, E , is not independent of these two. In fact it can be shown that the simple relation

$$E = \frac{9nk}{3k + n}$$

must hold true among these three quantities.

It has been said above that when a bar is exposed to simple longitudinal tension its diameter diminishes simultaneously with the increase of its length. Let the absolute diminution of the diameter be divided by the diameter itself, and the absolute increase in the length be divided, similarly, by the length itself; and let these two quotients be designated, respectively, as the "lateral contraction," and the "longitudinal dilation." The ratio of the lateral contraction to the longitudinal dilation is an important physical quantity, which is called "Poisson's ratio," after the French mathematician Poisson, who studied it extensively. Mallock found it to be 0.253 for steel, 0.325 for brass, 0.348 for copper, 0.375 for lead, 0.50 for india rubber and paraffin, and zero for cork. Poisson and Navier concluded from erroneous mathematical reasoning that the ratio in question is precisely 0.250 for all iso-

ELASTIN — ELATERIUM

tropic bodies, and in this they were followed by Cauchy and many other distinguished authorities. It may be shown, however, that Poisson's ratio is expressible in terms of the bulk modulus and the modulus of rigidity by means of the formula

$$\text{Poisson's Ratio} = \frac{3k - 2n}{2(3k + n)}$$

This expression cannot be numerically equal to 0.250, unless the modulus of rigidity is precisely three fifths of the bulk modulus — a relation that could not be assumed to hold true generally, and which we know, from experiment, to be false for multitudes of bodies that are sensibly isotropic. The wide range of values observed by Mallock therefore corresponds, in all probability, to a similar variation in the actual value of the constant, and cannot be safely attributed to errors of experiment.

The various moduli to which reference has been made have been determined experimentally for many substances. They differ appreciably in different specimens of the same substance, being influenced both by the chemical composition and by the physical state of the specimen tested. In the following short table values are given that will apply with a fair degree of accuracy to the average specimens of steel, brass, and glass that are likely to be met with in practical problems:

Modulus	Substance		
	Steel	Brass	Glass
Young's.....	30,000,000	14,000,000	7,200,000
Rigidity.....	12,000,000	5,200,000	2,900,000
Bulk.....	26,000,000	14,000,000	5,800,000

In this table the unit of length is the inch, the unit of force is the attraction that the earth exerts upon one pound of matter, and stress is supposed to be expressed in pounds per square inch. The several moduli here given do not strictly satisfy the formula given above for expressing Young's modulus in terms of the bulk modulus and the modulus of rigidity; but that is because they are averages of numerous results, taken from a variety of sources, and it appears to be better to give the experimental averages just as they were obtained, rather than to manipulate them so as to bring them into precise conformity with the formula. The formula itself is sufficiently trustworthy to serve for the calculation of any one of the three moduli of a given substance, when the other two moduli of that substance are known. Consult for further numerical data Rankine, 'Useful Rules and Tables'; and Everett, 'Units and Physical Constants.' In the latter book the data are given in the C. G. S. system.

Elastin, an insoluble proteid substance, of which the elastic fibres of connective tissue are composed. It may be conveniently prepared from the *ligamentum nucha*, by boiling with ether and alcohol (to remove the fats), and afterward by prolonged boiling, successively, with water, strong acetic acid, and concentrated caustic soda, and subsequent successive treatment with weak acetic acid, water, hydrochloric acid, and water. When so prepared, elastin is not soluble (without decomposition) in any known solvent. It dissolves with decomposition

in concentrated sulphuric acid, however, yielding leucin, but not tyrrsin. Elastin is digested both by pepsin and by trypsin, and it contains no sulphur. Its percentage composition, according to Muller, is: C=55.45; H=7.41; N=16.19; O=20.89.

Elate'a. See CITHÆRON.

Elater, ěl-ā-tēr, a genus of beetles in the pentamerous sub-order, type of the family *Elaterida*. They are familiarly known as "click-beetles" or "skip-jacks," from their habit of jerking themselves with a slight noise into the air when they land or are placed on their backs. The body is arched upward and suddenly straightened with a violent muscular exertion, which lifts the animal from the ground. The legs are too short for the ordinary method of righting the body. The larvæ are only too familiar as "wireworms" (q.v.). Some tropical forms are phosphorescent. See FIREFLY.

Elateridæ, ěl-ā-tēr'i-dē, a family of *Coleoptera* (click-beetles), tribe *Pentameræ*, sub-tribe *Sternoxia*. It contains the insects placed by Linnæus in his great genus *Elater*, now broken up into many genera. See CLICK-BEETLE; FIREFLY.

Elat'erin, a neutral chemical substance having the formula $C_{20}H_{28}O_6$, and obtained by alcoholic extraction of the greenish precipitate thrown down by the juice of the slightly unripe squirting cucumber, *Ecballium elaterium*. It crystallizes in hexagonal tablets which melt at 400° F., and are insoluble in water, but soluble in chloroform and in hot alcohol. Elaterin has a bitter taste, and is a powerful purgative, the dose being from the 40th to the 10th of a grain. A crimson color, changing to a scarlet, is produced when sulphuric acid is added to a solution of elaterin in carbolic acid; this reaction serving as a test for its presence.

Elat'erite, an elastic, asphalt-like mineral, known as "elastic bitumen." In color it is dark brown, with a specific gravity ranging from 0.9 to 1.2. It occurs abundantly in Derbyshire, England, and a mineral closely allied to it has been found at Woodbury, Conn.

Elaterium, ěl-ā-tēr'i-um, a mixture of principles formed as a precipitate, occurring spontaneously in the juice of the fruit of the wild or squirting cucumber, *Ecballium elaterium*, the active principle of which is elaterin. The squirting cucumber is a small perennial, of the cucumber family, indigenous in Persia, India and the warmer Oriental countries, and has been extensively cultivated even as far north as England. The fruit itself is 1½ to 3 inches long by 1-3 to 3-4 of an inch, oblong or oval in shape, covered with soft bristles, and yellowish green in color. It is firm externally. As the fruit ripens fermentation takes place in the interior with the formation of gas. This accumulates in sufficient quantities to exert considerable pressure, bursting the fruit at its base and squirting the seeds some distance. In this manner the fruit is distributed. Elaterium has been used for centuries as a cathartic, the phenomena of the squirting seeds having suggested its function. Elaterin itself is an neutral principle of the formula $C_{20}H_{28}O_6$. It forms in minute white prismatic crystals, without odor and with a slightly gritty and bitter taste. Elaterin is one of the most active of all the hydragogue cathar-

tics. It operates with violence even in minute doses. It is particularly of service in conditions in which there is general dropsy and no inflammatory condition of the intestinal tract. Elaterin is given in doses of from 1-40 to 1-10 of a grain.

Elba (Lat. *Ilva*; Gr. *Ætalia*), a small island belonging to the kingdom of Italy, in the Mediterranean Sea, off the coast of Tuscany, and with several much smaller isles, lying at the mouth of the Gulf of Piombino. The island of Elba is 18 miles from east to west, with a width varying from $2\frac{1}{2}$ to 12 miles in its widest part. The mountainous districts of the island yield large quantities of superior iron, marble, lodestones, and alum, besides wines and fruits. On the first abdication of Napoleon in 1814, Elba was assigned to him as a residence and empire. Here he accordingly took up his residence, in the month of May; and on 26 Feb. 1815, he secretly left the island, and, landing in France, began that brief and final career, known in history as the "Hundred Days." Elba was a place of celebrity in the time of the Romans, and famed then, as now, for its yield of iron. Two good ports are Porto-Ferraio and Porto-Longone, both well fortified. Pop. 25,480.

Elbe, ěl'bě (ancient ALBIS; Bohemian, LABE), a river of Germany, one of the largest in Europe. It rises on the southwest slopes of the Schneekoppe or Snowcap, one of the Riesengebirge, between Bohemia and Silesia. From this point it flows nearly due south into Bohemia for about 50 miles, when it turns to the west, and after about 40 miles takes a general north-northwest direction till it empties into the North Sea, intersecting Saxony, a considerable portion of Prussia, and in the latter part of its course separating Holstein on its right from Hanover on the left. The length, including windings, is upward of 780 miles. The principal affluents are on the right, the Iser, Schwarz-Elster, and Havel; on the left, the Alder, Moldau, Eger, Mulda, and Saale. In the lower part of its course the river is divided by five large and seven small islands into several arms, which unite again about five miles below Hamburg. The mean depth is 10 feet, average breadth 900 feet. It is more or less navigable for about 470 miles, but its estuary at Cuxhaven is much encumbered with sandbanks. It is well stocked with fish. On 1 July 1870, the navigation of the Elbe was declared free from Hamburg to Melnik in Bohemia. There is an important system of canal navigation in connection with the Elbe, Hamburg, for instance, being in this way connected with Berlin.

Elberfeld, ěl'běr-fěld, Germany, town in the Prussian Rhine province; 15 miles east of Düsseldorf, in the beautiful valley, and on both sides of the Wupper, enclosed by lofty hills. It has no historical or antiquarian importance. Its prosperity has been acquired mostly within the present century, and is due to the cotton manufacture, of which it is the central locality in Rhenish Prussia. In addition to the cotton manufacture, which, under a variety of forms, is the great staple of the town, linen, woolen, silk and mixed silk goods, ribbons, and velvet are extensively made, and largely exported. There are also numerous mills for spinning cotton twist, linen yarn, and worsted, and dye-works,

celebrated for the richness of their colors. The environs are almost covered with bleachfields. Pop. (1900) 298,884.

Elberfeld System, a system of poor-relief which originated in the appointment of six visitors in 1800, to investigate applications for aid, in the manufacturing town of Elberfeld, Prussia. The city was subsequently divided into districts, the number of visitors was increased, and the operations developed, until by 1852 what has become known universally as the Elberfeld System was adopted. Its main features are the division of the city into 26 districts subdivided into 364 precincts, each precinct being administered by an almoner who investigates each application, in cases of emergency provides immediate assistance, and as long as aid is afforded, visits the applicant twice a month. Money relief is granted fortnightly according to a fixed schedule, any earnings in the meantime being deducted; when needed, working implements are provided. A meeting of the almoners under the presidency of an overseer takes place every fortnight to discuss cases and to vote necessary relief, a report of the meeting being laid the next day before the directors who are chosen from four councilmen and four citizens with the mayor as chairman *ex officio*. The directors superintend and advise on the whole city's work. The positions of almoners, overseers, and directors are of a purely honorary character. The advantages of the system in the improvement of the condition of the poor have been strongly apparent, the ratio of persons assisted in 1889 being 7 per 1,000 as against 17 per 1,000 in 1855. See also CHARITIES.

Elberon, N. J., sea-coast summer resort in Monmouth County, on the Pennsylvania and the Central Railroad of New Jersey. Pop. (1901) 200. Here President James A. Garfield (q.v.) was taken' after he was shot by Guiteau, 6 Sept. 1881, and died here 19 Sept.

Elberton, Ga., city, county-seat of Elberton County; on the Southern and the Seaboard A. L. R.R.'s; 90 miles northeast of Atlanta. It is in a cotton-growing section and the chief industries are connected with the cultivating, shipping, and manufacturing of cotton. It contains manufactories for cottonseed-oil, cotton goods, compressing cotton, and for fertilizers for the cotton plant. The quarries nearby give employment to a number. Pop. 3,902.

Elbeuf, ěl'béf, France, town, in the department of Seine-Inférieure, 11 miles south-southwest of Rouen, situated in a beautiful valley on the left bank of the Seine. It has handsome churches, public buildings, and homes. It has spinning-mills, dye-works, and all accessories for the complete production of woollen manufactures, chiefly of lighter cloths, checkered stuffs, fine colored flannel fabrics, and all kinds of fancy goods. Pop. 40,500.

Elbing, Germany, seaport town, in West Prussia, on the Elbing, near its entrance into the Frische-Haff, 32 miles east-southeast of Dantzic. It is divided into the old and new towns, the former of which was once surrounded by turreted walls and gates, but these for the most part have been removed. It has ship-building yards, which do a considerable trade in building and repairing vessels. Its manufactures include cloth, leather, soap, tobacco, and beer.

By means of a canal it has connection with the Vistula, and the harbor was improved by the opening in 1884 of a mole 3,500 yards long. Pop. 50,121.

Elbow. See ARM.

Elbow Joint. See ARM.

Elbruz, ɛl'brooz, or **Elburz**, (1) A mountain range of Persia, running for 450 miles along the southern border of the Caspian Sea. It has a number of subordinate parallel ridges, enclosing extensive and fertile valleys; and unlike most Persian ranges, it has numerous prominent spurs, the highest peak being Mount Demavend (q.v.). (2) Elbruz is also the name of the loftiest summit of the Caucasus.

Elcano, Juan Sebastian de, hoo-än' sä-bäs-tē-än' dā älkä'nō, Spanish navigator: b. Guetaria, Guipuzcoa. He was captain of the Concepcion, accompanying Magellan and was the first to circumnavigate the world, completing his journey of three years 8 Sept. 1522. He went with Garcia Jofre di Loaysa on the westward voyage to the Moluccas, and died after passing the straits of Magellan and gaining the Pacific.

Elcesaites, ɛl-sē'sa-its, or **Elkesaites**, a sect founded in the 2nd century, during the reign of Trajan. They derived their belief from the teachings of the Book of Elkesai, supposed to have been inspired by an angel. Their system seems to have been a commingling of Oriental philosophy with Sudaism and early Christianity. Probably put into practice with the idea of satisfying the want of those persons seriously troubled by the religious chaos of the day caused by the mighty conflict of greater creeds. The followers of Elkesai or Elxai are often confounded with Ebionites (q.v.). The best account we have of the Elcesaites is given by Hippolytus in his chief work, 'Philosophumena.'

Elche, ɛl'chā (ancient ILLICI), Spain, town in the province and 14 miles west-southwest of Alicante, on the Vinalapo River. It is an ancient place, containing various Roman remains, also buildings showing the work of the Moorish architect. Dates, pomegranates, articles made from esparto grass, oil, leather, woolen goods, and wine are among the exports. Pop. 24,300.

Elchingen, ɛl'hing-ən, Bavaria, village, on the Danube, nine miles northeast of Ulm, which gave the title of Duke of Elchingen to Marshal Ney, who here defeated the Austrians 14 Oct. 1805. In the neighborhood are the ruins of a Benedictine Abbey of the same name, founded in 1128. There are two villages, Ober and Unter Elchingen, the former on the same hill with the abbey, the latter to the northeast of it. The hill on which the abbey stood was occupied by Mack, who had his headquarters in Ulm; while Ney, on the right bank of the river, repaired the bridge of Elchingen, forced the passage of the river, and took Elchingen by storm.

Elder, John, English engineer: b. Glasgow 1824; d. 1869. Educated in Glasgow, he was first employed as director of the drawing office of Napier's establishment, becoming later a member of the great ship-building firm which was known after 1860 as Randolph, Elder & Company, employing more than 4,000 men. His fame rests upon his invention of the com-

pound or combined high and low pressure engines, saving nearly 40 per cent of fuel.

Elder, Susan Blanchard, American writer: b. Fort Jessup, La., 19 April 1835. She was married to C. D. Elder of New Orleans. She began to write for the press, under the name 'HERMINE,' when quite young. She has published: 'The Loss of the Papacy'; 'James the Second'; 'Savonarola.' Her contributions to Roman Catholic publications are numerous, and her devotional poems are very popular. Her dramas are written for representation in Roman Catholic colleges.

Elder, William Henry, American Roman Catholic prelate: b. Baltimore, Md. 22 March 1819. He was educated at Mount St. Mary's College, Emmitsburg, and at the College of the Propaganda at Rome; and ordained to the priesthood in 1846. On his return to the United States he was appointed president and also professor of theology in Mount St. Mary's, where he remained till his consecration as Bishop of Natchez in 1857. During the Civil War he gave much of his time to the care of the wounded. When an order was issued by a post-commandant at Natchez, directing all clergymen to pray for the President of the United States, Bishop Elder refused to obey, on the ground that civil authorities could not change the form of the Mass. He was arrested and sent out of the diocese to Vidalia, La., but the order was soon revoked. During the yellow fever epidemic of 1878 in Mississippi he was in constant attendance on the sick till stricken with the disease himself. He was appointed coadjutor archbishop of Cincinnati in 1880; presided over the Provincial Council of Cincinnati in 1882, and on the death of Archbishop Purcell, the same year, became archbishop of Cincinnati.

Elder, Sambucus, a genus of shrubs or small trees and a few perennial herbs of the natural order *Caprifoliaceæ*. There are about 20 widely distributed species characterized by opposite, pinnate leaves, small white flowers usually in compound cymes, and black, red, white or green, juicy fruits (berries or drupes). Many of the species are used in ornamental planting, since they are readily propagated by root and stem cuttings, succeed well upon nearly all soils, are of rapid growth, graceful form, and are attractive both in flower and fruit. The best-known species in America is *S. canadensis*, the common or sweet elder, which is frequently seen in fence-rows, along roadsides, and on the margins of woods throughout southern Canada and the greater part of the United States. It attains a height of 10 feet or more, bears abundant fragrant flowers in midsummer and black berries in early autumn. These fruits are used where they can be obtained plentifully for making pies and elderberry wine. Several horticultural varieties have been introduced for their golden or variegated foliage, and one variety with large fruits was introduced in 1890. The flowers are used for making a wine, a perfume, and a "water" used in confectionery. Economically this species ranks as a minor fruit. Like some other members of its genus, it has also been used in medicine, but is rapidly giving place to other drugs. Probably *S. nigra*, the common European elder, ranks next in importance. It is much larger, often attaining a

height of more than 20 feet. The yellow, hard, tough wood is readily polished and is used for making skewers, fishing-rods, needles for making fish-nets, and as a substitute for boxwood. It is also employed for the same horticultural and economic purposes as the preceding species, and has numerous fancy-leaved varieties. Other well-known species are the scarlet elder (*S. racemosa*), an Old-World species, and the red-berried elder (*S. pubens*), a native of North America, considered by some botanists to be identical. There are also several unrelated plants which are popularly known as elder, as box-elder (*Negundo aceroides*), wild elder (*Aralia hispida*), also known as bristly sarsaparilla, and marsh-elder (*Iva frutescens*).

Elders, among Calvinistic churches, a body of men elected by the communicants from among their number to aid the minister in portions of his spiritual work. With the minister, they constitute the executive of the congregation. Among the Jews the elders are the rulers or magistrates of the people. The instinct of mankind considers the old fitter than the young to rule, and at first probably every "elder" was really pretty well advanced in life; but the designation ultimately came to be used more of office than of age. "The elders of the congregation," or simply "the elders," are mentioned as early as Lev. iv. 15. Seventy of them were appointed as associates of Moses (Num. xi. 16). They are combined with the officers (Deut. xix. 12), with the princes (Ezra x. 8), with the priests (Lam. i. 19). In the New Testament they are described as having given currency to traditions (Matt. xv. 2), and taken a chief part in compassing the death of Jesus (Matt. xxvi. 59; xxvii. 20), etc. There were elders, also, of single towns, as of Succoth (Judges viii. 14), and of Jezreel (2 Kings x. 1).

Eldon, John Scott, EARL OF, English jurist: b. Newcastle 4 June 1751; d. London 13 Jan. 1838. He was educated at Oxford; was called to the bar in 1776, and in 1782 was made king's counsel. Next year he entered Parliament, supported Pitt, and was made solicitor-general and knighted. In 1793 he became attorney-general, and in 1799 was created chief justice of the court of common pleas, and raised to the peerage and the House of Lords under the title of Baron Eldon. He became lord chancellor (1801), and retained this post under the subsequent administration of Pitt until the death of the latter in 1806. A year later, however, he resumed the chancellorship under Liverpool, and held it without break for 20 years. In 1821 he was created an earl by George IV. On the accession of the Canning ministry in 1827 he resigned the chancellorship, and never again held office. As a lawyer he was a master of English jurisprudence; as a politician he was opposed to reform. See Campbell, 'Lives of the Lord Chancellors'; Tuiss, 'Public and Private Life of Lord Eldon' (1844).

Eldo'ra, Iowa, city, county-seat of Hardin County, near the Iowa River, on the Iowa Central, and the Chicago, I. & D. R.R.'s; 122 miles west of Dubuque. The region is rich in deposits of clay, and brick making, the manufacture of tiles and sewer pipes are the chief industries. Pop. (1900) 2,233.

Eldorado, ɛl-dō-rä-dō (from the Spanish *El Dorado*, the Gilded Man), the region of un-

discovered treasure in South America. In the article DABAIBA we have traced the famous Eldorado myth back to those stories which, at the beginning of the 16th century, were current among the Indians of Darien about "a temple lined with gold," and have shown why the Spanish explorers failed to recognize in distant Cuzco, with its temple of the sun-god, the real basis of such accounts. The name Eldorado, however, with which the ever-receding or shifting territory, the subject of all those stories, has been stamped, was at first not the name of a place but of a person; and the name-giving addition to the myth is localized very precisely in the table-land of Bogotá, as follows: Lake Guatavita (north of the present capital of Colombia; elevation above sea-level 3,199 metres) was regarded by Indian tribes dwelling in that neighborhood in the 15th century as a holy place, and pilgrims who resorted to it often cast their offerings of gold and emeralds into its waters. Whenever a new chief of Guatavita was chosen, nobles and priests of his tribe bore him to the lake, as A. F. Bandelier has written, "upon a barrow hung with disks of gold. His naked body was anointed with resinous gums and covered all over with gold-dust." The chief plunged into the lake; spectators made the usual offerings of gold and jewels; and, on the conclusion of this ceremony of consecration, the new ruler and his subjects went down to dance and feast in Guatavita village. The Chibchas, (q.v.) conquered Guatavita about the end of the 15th century, and under their general government this extraordinary local custom had been discontinued for a number of years before the first Spanish settlements were made on the Caribbean coast—there was no longer an independent Guatavita chief to signify his acceptance of the local religious beliefs in a fashion so dramatic; but native folk-lore continued for a century, at least, to make much of this glittering symbolic figure and the sacred lake. In 1529, Dalfinger, governor of the German colony in Venezuela, set out from his little capital of Coro, and probably reached the edge of the high plain of Bogotá by way of the Magdalena River; there the resistance of the Indians obliged him to turn back. Four years later the report of the vast treasure secured by the conquerors of Peru (Atahualpa's "ransom" alone was officially valued at 3,933,000 ducats of gold and 672,670 ducats of silver) appeared to justify ventures undertaken in reliance upon the wildest Eldorado tales. It is also true that a fresh outbreak of the gold-fever affected the Spanish colonists everywhere in America, more or less, but especially those in the agricultural settlements (Compare: DOMINICAN REPUBLIC, sub-title *History*); and that leaders of those colonies, in order to retain their men, were obliged to make fresh efforts to find treasure. In Santa Marta, an expedition was organized to ascend the Magdalena River to the highlands; at Coro, Georg von Speyer organized a campaign for the exploration of the Meta plain, far inland. The former expedition under command of Quesada in 1537 reached the old home of the gilded chief; and although Guatavita either hid its gold or was actually poor (40 years having passed since it had ceased to be a place of pilgrimage), the treasure collected in this neighborhood, principally at the villages of Tunja and Iraca, was officially valued at 246,676 pesos in gold, or

ELDRIDGE — ELEANOR OF AQUITAINE

about \$1,200,000, besides 1,815 emeralds. Von Speyer went astray among the tributaries of the upper Orinoco, but his lieutenant, the German, Nicolaus Federmann, leading a company from Coro, reached the Bogotá highlands in time to meet there not only Quesada but the conqueror of Ecuador, Benalcázar, who came up from the south, having also heard the story of the Gilded Man. Each of these leaders considered himself the discoverer of the country, and they proceeded together to Spain, to submit their claims to the Spanish court, leaving their forces to hold the Eldorado which had been despoiled by the Chibchas, ransacked by themselves.

We are, therefore, unable to agree with Bandelier when he says that, after this time, "Transplanted by the over-excited imagination of the white men, the vision of the *dorado* appeared, like a mirage, enticing, deceiving, and leading men to destruction on the banks of the Orinoco and the Amazon." The Gilded Man had been located, and that part of the myth was buried. Subsequent explorations were planned to discover rich countries which were Eldorados only in the modern sense of the word; and we find that the word was used with nearly its present signification at the time when the Amazon River received its name. The legend is especially noteworthy in connection with the history of the Venezuelan settlement under the direction of the German Welsers. Having received the province from the Spanish crown practically as a mortgage security for money loaned, Welsch and his associates tried to recover the advances they had made from the revenues of the district; and since the coast lands were found to be less profitable than they had expected, they engaged in one Eldorado expedition after another. Dalfinger, Federmann, and Von Speyer have been mentioned; before the utter ruin and failure of the colony at Coro, Von Hutten's expedition penetrated to Omagua, a region near the Amazon, west of Rio Negro and the Cassiquiare. The Spanish conquerors of Peru and Ecuador were led by the search for further stores of wealth to make the most important geographical discoveries east of the Andes. Gonzalo Pizarro set out from Quito to explore the forests (1539-42), hoping to find spices there, and also "wealthy regions in which the people went around adorned with gold." His lieutenant, Francisco de Orellana, with 53 men in a bark, becoming separated from the main body of the expedition, went on down the Amazon to its mouth. The Dominican Carvajal, Orellana's chronicler, relates that women took part in the fighting against the Spaniards, and that a captive Indian spoke of a tribe of Amazons rich in gold living north of the river. (Compare Prescott's 'Conquest of Peru,' II., 164-5, note). Wandering Indians brought to Peru about the middle of the 16th century reports of countries rich in gold and silver, which lay far eastward; and the viceroy made use of the Eldorado fever thus excited to rid Peru of a large number of disorderly persons. In 1560 a company of criminals and desperados, with women, set out from Santa Cruz de Capacocha, proceeding in boats, canoes, and even upon rafts, down a tributary of the Amazon, under the leadership of Pedro de Ursua. In January, 1561, Ursua was murdered by conspirators, and eventually Aguirre, chief con-

spirator, transformed the remnant of the expedition into a piratical band; captured the island of Margarita, and invaded Venezuela. At least four Eldorado expeditions proceeded from the north coast toward the interior before the end of the century, in addition to that one which Sir Walter Raleigh led in 1595. Consult: Bandelier, 'The Gilded Man' (New York 1893), and Brinton, 'The Myths of the New World' (New York 1868).

MARRION WILCOX.

Eldridge, Shaler W., American abolitionist: b. West Springfield, Mass., 1817; d. Lawrence, Kan., 17 Jan. 1899. He removed to Kansas in 1855, and became proprietor of the American House in Kansas City, soon recognized as the headquarters of Freesoilers. In 1856 Eldridge opened the Free-State Hotel in Lawrence, but soon afterward a pro-slavery court issued a writ of indictment, declaring the place a nuisance, and it was destroyed by a posse led by Sheriff Jones. This occurrence caused great excitement among the Freesoil men, who commissioned Eldridge to visit Washington with a petition in their behalf, and also to sit in the convention that nominated Fremont. Later he became a member of the National Republican Committee and agent to promote immigration into Kansas. Under the last authority he led a large number of settlers to Kansas. During one of these trips, with a party of 350 men, he was taken prisoner by United States troops. Subsequently he recruited a party of Freesoilers, who retook the arms from the United States officers at Leecompton. He was instrumental in giving much aid to the Free-State cause by smuggling large amounts of ammunition and provisions into Kansas Territory. During the Civil War he served in the Union army.

Eld's Deer, a deer (*Cervus eldi*) native to the Malayan region. It is about four feet tall, lives in swampy places, and is often found in large herds. Its habits are like those of the Indian swamp-deer. The antlers are peculiar in that the brow-tine sweeps down over the forehead and that the upright part has numerous points.

Eleanor of Aquitaine, queen of France and afterward of England: b. 1122; d. Fontevrault, France, 1 April 1204. She was the eldest daughter and heiress of William IX., Duke of Guienne or Aquitaine, and was married 2 Aug. 1137, to Prince Louis, who in the same year succeeded to the throne of France as Louis VII. She was gay, frivolous, a lover of poetry and art, and could not sympathize with the ascetic spirit of her husband. She accompanied him on the second crusade to the Holy Land in 1147. At that time he complained of her preference for other men, and on their return from Asia they were divorced 18 March 1152. A short time afterward she bestowed her hand upon Henry Plantagenet, the future Henry II. of England. This alliance, which made Henry master of Eleanor's vast possessions in France, produced pernicious and protracted wars between France and England. She bore him many children, but his infidelities and neglect changed her love into hatred. She incited her sons Geoffrey and Richard to rebel against their father, was imprisoned in 1174, and remained in confinement until after Henry's death in 1189, when she was released by

ELEANOR CROSSES — ELECTIONS

his successor, Richard I., who placed her at the head of the government on his departure for the Holy Land. She negotiated his marriage with the daughter of the king of Navarre, and went to Germany with his ransom from captivity. She afterward retired to the abbey of Fontevrault, and surviving Richard, lived to see him succeeded by one of her other sons, John Lackland, the signer of Magna Charta. She was a favorite personage with the troubadour poets of the day, and appears in a very different light in their works from that in which she is represented by French and Norman chroniclers.

Eleanor Crosses, memorials of Eleanor of Castile. She was the wife of Edward I. of England, and d. Lincolnshire 1290. Her body was taken to London by her sorrowing husband who subsequently erected a monument, terminating in a cross, at every spot where her funeral train had rested. These places were Lincoln, Grantham, Stamford, Geddington, Northampton, Stony Stratford, Woburn, Dunstable, St. Albans, Waltham, East Cheap, and Charing Cross, but the list varies slightly as given by different authorities. The crosses at Geddington and Waltham remain, although considerably altered by restoration in the latter case. That at Charing Cross, destroyed in 1647, was replaced in 1863 by a new one reproducing the original.

Eleatics, ē-lē-ăt'iks, a Greek sect, so called because founded at Elea, in Sicily, by Xenophanes of Colophon, about 538 B.C. Zeno, who flourished 464 B.C.; Empedocles, 435 B.C.; and Melissus 428 B.C., were leading philosophers of this school. That which from the commencement distinguished the Eleatic school from the Ionic was its method, which in the one case was dialectic, in the other empirical. Starting from the observation of external nature, the Ionians endeavored to discover some elementary principle, as water, air, fire, or a combination of elements, by the action of which the phenomena they observed might be accounted for. The Eleatics made the abstract idea of Being or God, deduced from the contemplation of the universe as a whole, their starting-point; and their reasonings sometimes led them to deny the reality of external phenomena altogether. This was the result of the development which the principles of Xenophanes received from his followers Parmenides and Zeno, the latter of whom denied the existence of variety in any form, including that of the world and even of movement. See IONIANS; XENOPHANES; ZENO.

Eleazar, ēl-ē-ă'zār (Heb. "God hath helped"), the third son of Aaron, and high priest after him (Ex. vi. 23; Num. xx. 25-28). The high priesthood continued in his family through seven generations, till the time of Eli, when we find it transferred to the line of Ithamar. In the reigns of Saul and David it was restored to the line of Eleazar, and so continued till after the captivity.

Elecampane, ēl-e-kām-pān' (*Inula helenium*), a plant of the sunflower family (*Compositæ*). The stem is three or four feet high, thick, pubescent, and branching above; the radical leaves are often two feet or more in length; the flowers are large and yellow. The plant is a native of Europe and Asia, naturalized in the United States. It grows abundantly along roads and in waste places. The root is perennial, and

has a bitter aromatic taste. Elecampane is cultivated occasionally as an ornamental plant, and the flowers are sometimes used to adulterate arnica. The root was formerly much employed in medicine, but has fallen into disuse. It contains a number of active principles, the most important being a volatile oil, inulin, which is a form of starch, and a camphor, helenin. By reason of the camphor and the oil the action of the drug is somewhat stimulant and stomachic. Elecampane was once very much used in the treatment of bronchitis and amenorrhœa. As a hot infusion it subserves practically the same purpose as camomile tea, being a good diaphoretic.

Election, a word used in astrology in the plural form, and meaning certain opportunities of times, elected (or chosen) by astrological observations, as most fit for a particular business or enterprise.

In theology, the word (singular) is applied to the act of God in selecting some persons from the race of man to be regenerated by his spirit, to be justified, to be sanctified, and to receive other spiritual gifts in this world, with eternal life in the next. The Calvinistic doctrine makes this election take place by God's mere good pleasure, without any foreseen merit in the individuals chosen. The Arminian one considers that God chooses those who he foresees will accept the offer of the Gospel and act as true Christians till death. The third chapter of the Westminster Confession, entitled "Of God's Eternal Decree," uses more decided language. The strongest adherents of this view are in the Presbyterian churches, though there is a tendency to soften the harsher features of the system. Many Baptists hold the same doctrine, as do the Calvinistic Methodists.

Elections. In early colonial days, local officials in New England were chosen in town meeting, much as they are to-day. Nearly all those of the southern colonies were appointed. In New Amsterdam (now New York), the right to elect its own magistrates was long refused by Director Stuyvesant. "If," he said, "the nomination and election of magistrates were to be left to the populace who were the most interested, then each would vote for some one of his own stamp, the thief for a thief, the rogue, the tippler, the smuggler, for a brother in iniquity, that he might enjoy greater latitude in his vices and frauds."

The illicit use of money in elections began almost at the beginning of political history in America. Rhode Island, for instance, found it necessary to pass a general act against bribery and corruption in 1737, and 10 years later replaced it with one even more stringent. Judging by its provisions the evil must have been alarmingly prevalent in that colony. To this day Rhode Island is the New England State where most complaint is made of the same evil. The other New England colonies found no such laws necessary, but all the rest had them save New York and Maryland. In England the purchase of votes was for centuries as natural a thing as the sale of boroughs, and no serious attempt to prevent it was made till 1854, when the Corrupt Practices Prevention Act defined bribery, forbade certain petty expenditures, and required the making public of election expenses of a cer-

ELECTIONS

tain character by proper returns. This and further legislation did not remedy the evil materially, and in 1883 a much more drastic measure was adopted, which has been the model for legislation elsewhere. The novel and essential idea in it was the naming of an election agent by each candidate, and the holding of him responsible for publicity as to expenditure. Such American States as have copied this device, have rendered it futile by failing to copy the further proviso found in England, definitely limiting expenditure, with the penalty of invalidation of election in the case of any proved excess. An English candidate standing for a borough of 2,000 electors may not disburse, either by himself or through his agent, a sum exceeding £600; for every additional thousand electors, an extra £30 is permitted. In the counties, where the area is wider and the inevitable expense larger, £630 is the limit for a register of 2,000 electors, with an increase of £60 for every additional thousand. Contrast this with the situation in American congressional districts, where expenditures of from \$10,000 to \$100,000 by candidates are far from unknown. It is estimated that the total party expenditure in the last national campaign was well over \$5,000,000, to which figure it had grown from \$100,000 spent to elect Lincoln in 1864. Add to this the money used for the thousands of candidacies for minor places, and it is clear that the total is so enormous as to make adoption of the complete English reform almost inevitable in the near future, for though a great part of the outgo is for what are conventionally considered legitimate purposes, the mere fact of its size and growth is enough to compel legal limitation if America is not to become a plutocracy. At present a lukewarm public opinion attaches little disgrace to electoral corruption, and easily condones the offense of the public official who indirectly recoups his election expenses out of the public treasury. Therefore, almost in vain do halfway reformers pile penal statute upon penal statute. The Massachusetts law has 56 sections of election penalties, and it is typical. Three years after the passage of the New York Reform-ballot Law in 1890, investigation by a public-spirited committee of 50, together with the finding of more than 60 indictments by the grand jury, demonstrated that false registration, false voting, and bribery were as easily and safely practised as they ever were, and that perjury had enormously increased, owing to the number of safeguards which must be sworn away by the fraudulent voter and the collusive inspector. But deplorable as are all these facts, it is on the other hand true that the great majority of the members of our various legislative bodies, as well as our elected officials, are honestly elected. The diminution of corrupt practices is one of the benefits expected from the use of voting machines. (See **BALLOT**.) False counting of ballots has been an easy and common way to vitiate election results. In many a city ward the election officials return any majority the boss desires. Though the evil has been lessened in some of the States by strict laws, under the strictest of them it is still possible for knavish counters to nullify ballots by adding marks, and the lawmaker cannot keep pace with the shrewdness of the trickster. Furthermore, it is believed that the errors of machinery are likely to be in the aggregate far less damaging

than those made under the present system by the voters themselves. In a contested election case in New York the court estimated that an average of five ballots had been rejected as defective in each election district in the preceding election. In 1895, in the city of New York, out of a total in round numbers of 300,000 votes cast, 9,283 were defective, and 20,400 were blank. Of the 412,319 men who voted in the Massachusetts State election of 1902, 13,630 failed to have a vote for governor recorded, some, no doubt, with intention, but many through carelessness.

Another potent source of election evil is found in faulty methods of identifying the voter. The fraud that results takes the form of "impersonation" (voting on another man's name), or "repeating" (voting more than once). To lessen the likelihood of these crimes, some States require every voter to establish anew each year his right to vote; others allow a name once on the lists to stay there till death or removal causes it to be dropped. With our dread of red tape and formalities, we hesitate to adopt the ultimate remedy, that to be found in France, where every man, as he steps up to the ballot-box, must produce his "electoral card," on which are inscribed his full name, profession, and residence. This card is issued by the mayor of the town where the voter lives, after the latter has established his identity and majority by the production of a properly attested "act of birth." Each electoral card is numbered, and when it is presented at the polls, the judge of elections takes it, and calls off the number and name, while two other judges, with the official poll list before them, repeat aloud the number and name and check off on the register. Then, and not till then, the first judge accepts the ballot from the voter and drops it into the box; and before handing back the card, he tears off a corner of it, which renders it useless for further voting that day. These bits of card are strung on a wire and are counted, at the close of the polls, to see if they tally with the number of ballots in the box. See **BALLOTS**.

Under prevailing methods the views of large numbers of voters are not represented by men of their choosing. Minority parties get a voice in legislative assemblies only by the haphazard preponderance of their members in a few localities. In every voting district that group of electors which is in the minority has no direct representation, and sometimes for a generation its members will go to the polls in vain. Though Norway, in its constitution of 1814, appears to have been the first country to make an attempt to change this, the subject did not attract general attention till toward the middle of the century. In 1844 Thomas Gilpin published in Philadelphia a pamphlet that led a long train of literature, and in 1857 appeared the first of several books by Thomas Hare, in whose idea of "personal representation" J. S. Mill thought he discovered "the greatest improvement of which the system of representative government is capable." Since then many plans to accomplish the same end have been suggested. All presuppose that more than one place is to be filled at a time, as a board of aldermen to be elected on a general list, or several representatives from one district. The simplest plan is the single-vote system, where each elector has but one vote and the

ELECTIONS

candidates getting the largest number of votes are declared elected. It has been used in Philadelphia by the Republican party in the election of ward executive committees, and by the Democratic party in choosing inspectors of election. It is the method justified by the theory that no voter is entitled to be represented in any representative body by more than a single representative, and would seem admirably adapted to the conduct of the internal affairs of parties. On the other hand, where the supremacy of party views is the issue, it is manifestly objectionable, as without an impracticable degree of party machinery and discipline, the majority party, if it has nominated as many candidates as there are places to be filled, many so scatter its votes that less than half of them will be elected, and in any event cannot allot its votes so as to make sure of a result proportionate to its preponderance. Systems based on the "limited vote" theory meet this objection to some extent. Under them each voter may vote only for some fixed number of candidates less than the number to be elected. In operation this secures representation to the minority party second in rank, but with no relation to its numerical importance, and smaller minority parties get no representation at all. A modification of the idea was embodied in a law passed by the Massachusetts legislature in 1903, providing that each political party shall nominate 8 candidates for the board of aldermen in Boston; as 13 are to be chosen, this is expected to secure that not more than 8 shall be of any one party. With the next group of systems, those known as "cumulative," arithmetical complications grow. The first practical test of the idea came in 1870, when it was adopted as the method of electing English school boards, and in the same year it was put into the Constitution of Illinois by the proviso that "each voter may cast as many votes for one candidate as there are representatives to be elected, or may distribute the same or equal parts thereof among the candidates as he shall see fit." To each legislative district were allotted three members, so that a voter could cast his three votes for one, a vote and a half for each of two, or one vote for each of three. A mass of testimony on the practical working of the system, collected by M. N. Forney in 1893, indicated that on the whole the people of the State deemed it decidedly advantageous, yet far from perfect. Unquestionably it secures its object, the representation of minorities; in 1892 there was not an Illinois district in which any one party elected all three representatives. The chief objection comes from the chance and temptation for members of the majority to "plump," that is, cast all three votes for one man: sometimes this permits the minority to elect two men, when the bulk of the majority vote is concentrated on one popular candidate; therefore it invites to contests between party colleagues instead of political antagonists, breeds jealousies, and disrupts organizations. These evils have been more conspicuous in the choice of English school boards, for the more men to be elected, the greater the dangers from "plumping." The wasteful accumulation of votes for the more popular candidates or those of the more powerful factions, has permitted small factions to secure the election of members when not really entitled thereto by their numbers, and thus have

let in weak or mischievous men. To guard against this by the *proportional* representation of minorities, systems of three varieties have been devised. The first, known as the "free list" plan, provides that the lists of candidates shall be made up by the parties before the election, and that the seats to be filled shall be divided between the parties in the proportion of the total votes cast by each, the higher men on each list to be declared elected to the number their party proportion warrants. This system has been in use in some of the Swiss cantons, and Belgium enacted it into law in 1899. Its weakness is that it makes election wholly a party matter, practically preventing independent candidacies. A "freer list" plan advocated by William H. Gove of Salem, Mass., provides that the lists shall be made up by the candidates, rather than by the parties. In advance of the election the candidates are to designate who shall get the benefit of any ineffective votes cast for them. When the votes are counted, the first step is to divide the total number of ballots by that of the places to be filled; the quotient determines the number of votes a candidate must get in order to be elected,—his "quota." Votes cast for any one man beyond his "quota" are ineffective, and are ignored, so far as he is concerned, but are to help some other candidate, and the same is true of votes for candidates receiving so small a number that they must fail of election. The "freest list" system, the Hare plan, has the list of preferences made up by neither the party nor the candidate, but by the voter, who designates on his ballot the order of his choice. In the counting, as soon as it appears that a first-choice candidate needs no more votes, the second-choice candidate moves up into his place, getting credited with the ballots until he in turn has reached his quota, and so on. Though advocated by very many able men, from Mill on, the quota plans have as a rule failed to pass beyond the first critical point, legislative comprehension. Like all other plans for minority representation, too, they run counter to the belief, ingrained in Anglo-Saxon communities especially, that only the majority has a right to share in the work of representative government. Furthermore, the English and American adhesion to the two-party idea renders it probable that minority representation will make the more headway among the continental nations, accustomed as they are to government by groups. In America its most promising opportunity is in the choice of local legislative bodies where partisanship on national lines may sometimes disappear.

There is no legal, philological, or popular agreement as to the use of the word "majority" in matters of election. In computation it may mean the amount by which the greater number exceeds the less, if but two numbers are compared; or the amount by which the greatest number exceeds the total of the lesser numbers; or the amount by which the greatest number exceeds the next to the greatest. For the last case we customarily use the word "plurality," but in England the normal designation is "majority," and candidates have been elected with regard only thereto from time immemorial. The weight of American usage restricts "majority" to excess of the greatest number of votes over the total of the rest, and we say that for a majority a total of one more than half is necessary. This prac-

ELECTIVE AFFINITY—ELECTIVE COURSES

tice dates from colonial times. In Massachusetts, New York, New Jersey, South Carolina, and Georgia, a majority seems to have been required; in other colonies as a rule a simple plurality sufficed. New York put the plurality rule into her Constitution of 1777, and most of the other States followed her example, but the belief in the virtues of an absolute majority lingered in the New England States till the middle of the following century.

Propositions to go back to the absolute majority plan are now very rarely heard, and in the matter of popular elections the subject still has importance only because the Constitution of the United States requires an absolute majority of electoral votes for the choice of President. In conventions the majority rule yet prevails, occasionally entailing hundreds of ballots, and in the Democratic national conventions a two thirds vote is required to nominate. In primaries and caucuses the plurality plan prevails by almost invariable custom, voters everywhere being unwilling to give the time required for repeated ballots. The courts have had various occasions to consider whether a majority of the votes cast at an election on any question means the majority of those who voted on that question. In 95 U. S. 369 the court held (Miller and Bradley, JJ., dissenting) that "all qualified voters who absent themselves from an election duly called are presumed to assent to the expressed will of the majority of those voting, unless the law providing for the election otherwise declares." But in 69 Ind. 505, where an amendment to the Constitution received less than a majority of all the votes at the election, but a majority of those cast for or against the adoption of the amendment, it was held (two judges dissenting) that the amendment had been neither ratified nor rejected. The celebrated action of Speaker Reed in counting for purposes of a quorum those present and not voting, is of course in line with the theory that a majority of those voting should prevail, and it is significant that his decision, much criticised at the time, has now been accepted by almost everybody as good parliamentary law.

The absence of voters from the polls is a recognized evil, for which the remedy commonly proposed is compulsory voting, secured by imposing penalties for failure to vote. Neither evil nor remedy is novel. In 1636 the general court of the Plymouth Colony provided that "for default in case of appearance at the election without due excuse, each delinquent to be amerced 3s. ster." The custom continued certainly beyond 1671, for in the revision of the laws then published, the fine was put at 10 shillings. Other colonies had like laws, Virginia maintaining hers throughout her history. Her first law on the subject made the fine 100 pounds of tobacco, and in 1662 this was increased to 200 pounds. Some of the New England towns fined freemen who came late to the town meeting. None of the States have revived the colonial idea, of a money fine, probably because the evil is diminishing, rather than increasing. It is of comparatively small moment now in our presidential elections, where five sixths of the voters take part, and the absence of a large share of the remaining sixth can be accounted for by sickness, age, accident, inclement weather, and other reasonable excuses, but it is still of unfortunate importance in State

and municipal elections, though even there diminishing. In Belgium, Switzerland, and some other European countries, punishments are inflicted on non-voters. In Belgium, for the first offense the culprit is at once cited to appear before a justice, who reprimands or fines him; the second offense is more severely punished, and the name of the refractory citizen is published by the magistrate and posted on the gates of the town hall. The man who, without excuse, has abstained from voting 4 times in 10 years is considered unworthy of citizenship; his name is stricken from the poll lists, and for 10 subsequent years he is debarred from holding any public office. Illinois has an ingenious penalty, putting on the jury lists the names of persons who fail to vote. It might be expected that this would benefit the suffrage more than the jury system. One of the proposed forms of punishment is that the voter who once omits to vote shall not be allowed to vote thereafter until he shall have purged himself by paying a fine, but this would be no hardship to most of the apathetic citizens.

Besides the specific remedies in process of application or proposed for the cure of the evils our methods of election have developed, there are general reforms of many kinds with this as their purpose in whole or in part. One of them is the movement for lessening election evil by lessening elections, which has prevailed in nearly all the States to the extent at least of substituting biennial for annual elections. Another seeks improvement by having State and municipal elections on different days, and New York has gone so far as to put them in different years. Another, applicable only to municipal elections, looks to the abolition of national party lines in local affairs. Still another finds promise in the reduction of the number of elective offices. (As to the methods of nominating candidates, see CAUCUS; and for further information upon this subject, see BALLOT; POLITICS; etc.)

ROBERT LUCE,
Chairman House Committee on Elections, Massachusetts Legislature.

Elective Affinity, a term formerly used in chemistry, in connection with the supposed fact that when a given chemical substance is mixed with two or more others with which it is capable of combining, it will exhibit a preferential affinity for one of them, and combine with that to the exclusion of the others. This view of chemical action is now known to be incorrect. See EQUILIBRIUM, CHEMICAL.

Elective Courses and Elective Studies, as applied to colleges and universities in particular, and to all schools in general, may be defined broadly as that system of education which permits the student or learner to choose his own subjects of study during the time of attendance at school. The matter of allowing more latitude of choice to the individual pupil has attracted much attention in recent years, with the result that many radical changes have been

ELECTORAL COLLEGE—ELECTORAL COMMISSION

made in the courses of study in some of the colleges and universities in the United States. Formerly Harvard, Yale, and other American schools required that students should pursue certain studies in order to obtain the degree of bachelor of arts; and such restriction eventually led to the exclusion of all studies that did not contribute to the obtaining of the desired degree. Gradually the secondary schools adopted compulsory courses of study preparatory for colleges, and crowded out many of the studies that might fit the student for business life without going the college road. The special commercial, scientific, and art school came into existence to meet the wants and needs of a large number of students. Many of the leading schools of the United States have in recent years modified their courses of study, and to-day allow a choice of subjects. The new colleges, Leland Stanford, Jr., Chicago, Cornell, and others, have allowed from the first more freedom in the selection of subjects than was formerly permitted by the other schools. The "optional" or the "elective" system is not new; it was in existence in many of the leading schools in Mediaeval Ages and even earlier, and success and failure have attended the system according to the methods used in its enforcement. The strongest and best work in any school has been done where the needs of the individual have been taken into consideration. Where able instructors, those who understood human nature and its needs, have guided the immature student, or to use the modern term, where there were wise "advisers," the system was a success. The importance of the adviser is shown in the marvelous results accomplished by the independent schools which came into existence in the United States, especially in the West, about the middle of the 19th century. Thousands attended those schools, and with good results, because wisely directed and guided by capable, conscientious advisers. The pupil when left to his own discretion may choose studies "along the lines of least resistance," or "soft" courses, and may not select the studies necessary for the foundation of any system of education. Students of the maturity of mind required for entrance to Johns Hopkins or similar institutions cannot be compared with the younger pupils who constitute the freshman classes of the majority of our colleges. In order to ascertain what colleges and universities sanction elective courses it is necessary to obtain the latest changes direct from the college authorities. Consult: Burns, 'Elective System of Studies in Colleges' ('Catholic World,' Vol. LXXI., 366); Eliot, 'Educational Reform' (1898); Hanus, 'Problem of Electives' ('Popular Science Monthly,' Vol. LVIII., 58); Phillips, 'Electives in American Education' ('Pedagogical Seminary,' Vol. VIII., 206); Shaler, Thurber, and others, 'Elective Studies in Secondary Schools' ('Educational Review,' Vol. XV., 417); Thurber, 'Some Problems of the Elective System' ('School Review,' Vol. IX., 79).

Electoral College. See ELECTORS.

Electoral Commission, 1877. The electoral vote in the presidential election of 1876 showed 184 undisputed votes for Tilden; 163 for Hayes; four States with 23 votes—South Carolina, 7; Florida, 4; Louisiana, 8; Oregon, 3—sent in conflicting returns. If the Republicans

won all the contests, Hayes was elected by one vote. Of these States, the first three returned popular majorities for Tilden electors; but the "carpet-bag" governments in each had constituted "returning boards," whose function was to throw out enough Democratic votes, on the ground of intimidation of negro voters, to leave a Republican majority. Neither the reality of the intimidation, nor the arbitrariness of the assumption that but for it the negroes would all have voted and all voted Republican, is now disputed by either party. Oregon chose Hayes electors; but as the returning boards would give the Republicans the other three States, and therewith the election if upheld, the Democrats ousted a Hayes elector on a technicality and replaced him by a Tilden one, as a basis of compromise or a menace. Obviously, the Republicans could not compromise anything and win; and as they held the administration and the army, they could defy threats. The Senate was Republican, the House Democratic; there was therefore a deadlock on the admission of returns, as the 22nd Joint Rule, throwing out disputed States, had been repealed by the Senate 20 January for this very emergency. Finally, as an alternative to a most dangerous anarchy, both sides agreed on a joint commission to pass on all the contests; the Democrats being confident that it could establish no guiding principle whatever, of going behind the returns or not, accepting or rejecting State certificates as conclusive, which would not give them at least one of the disputed States. They underestimated the intellectual resources of their opponents. The Act creating the commission was approved 29 Jan. 1877; its decisions could only be reversed by concurrent action of both Houses. The body was to be composed of five members of each House and five associate justices of the Supreme Court; the latter as indicated were two Republicans and two Democrats, and were to select a fifth. The Senate appointed three Republicans,—G. F. Edmunds of Vermont, O. P. Morton of Indiana, and F. T. Frelinghuysen of New Jersey; and two Democrats,—T. F. Bayard of Delaware, and A. G. Thurman of Ohio, the latter taken sick and replaced by Francis Kernan of New York. The House appointed three Democrats,—H. B. Payne of Ohio, Eppa Hunton of Virginia, and J. G. Abbott of Massachusetts; and two Republicans,—J. A. Garfield of Ohio, and G. F. Hoar of Massachusetts. Obviously, therefore, the odd justice would have the deciding voice. The Republican judges were William Strong and Samuel F. Miller; the Democratic, Nathan Clifford and Stephen J. Field; they chose Joseph P. Bradley as the fifth. The counsel were—Democratic, Charles O'Connor of New York, Jeremiah S. Black of Pennsylvania, Lyman Trumbull of Illinois, R. T. Merrick of the District of Columbia, Ashbel Green of New Jersey, Matthew H. Carpenter of Wisconsin, George Hoadley of Ohio, W. C. Whitney of New York; Republican, W. M. Everts and E. W. Stoughton of New York, Stanley Matthews and Samuel Shellabarger of Ohio. Other lawyers appeared on special points. The States were taken up in alphabetical order,—Florida, Louisiana, Oregon, South Carolina,—and the vote upon each was eight to seven for the Republicans, on every contested point, Mr. Justice Bradley sustaining all the contentions of that side. The broad decision was, that Congress cannot, as it had done re-

ELECTORAL REFORM—ELECTORS

peatedly before, go behind the returns and take evidence as to the manner in which State majorities for electors have been obtained. On other points the decisions varied with the cases. In particular, the Democrats contended that the question as to the eligibility of an elector who is also a government official—a combination forbidden by the Constitution—was decided in two different ways within two days, on the Florida and Louisiana cases, in both to the profit of the Republicans; and Judge Bradley published a defense of his action. The court adjourned *sine die* on 2 March. The peaceful acceptance of the decision was much helped by the Democratic speaker, Randall of Pennsylvania, who firmly checked all Democratic attempts to "filibuster."

Electoral Reform. See ELECTIONS.

Electoral Votes, the votes cast by the presidential electors or electoral college for President and Vice-President. Prior to 1804 each elector voted for two candidates for President. The one who received the largest number of votes was declared President; and the one receiving the second largest vote, was elected Vice-President. The votes for the first President were: George Washington 69; John Adams (Mass.) 34, John Jay (N. Y.) 9, R. H. Harrison (Md.) 6, Jno. Rutledge (S. C.) 6, John Hancock (Mass.) 4, Geo. Clinton (N. Y.) 3, and scattering 7. In 1900 the electoral votes cast by the electoral college were as follows: For President, William McKinley, 292; William J. Bryan, 155; for Vice-President, Theodore Roosevelt, 292; Adlai E. Stevenson, 155. See ELECTORS; ELECTORAL COMMISSION.

Electors, German Imperial (Ger. Kurfürst), certain princes of the old German empire who had the right of electing the emperors. The number of the electors was early fixed at seven, including the archbishops of Mainz, Cologne and Trèves, the king of Bohemia, the count palatine of the Rhine, the duke of Saxony, and the margrave of Brandenburg. Later, electorates were given to Bavaria and to Hanover; in 1802 the Bavarian electorship had expired, the archbishops of Cologne and Trèves were excluded, and the number of electors was increased to 10 by conferring the rank on the rulers of Baden, Württemberg, Hesse-Cassel, and Salzburg. In 1806 the emperor gave up the imperial title, and the electors gradually adopted other titles.

Electors, United States Presidential (as a body, termed the Electoral College, a term informally used since about 1821, probably suggested by the college of cardinals; "college of electors" appears in the Act of 1845), the intermediate body for whom, and not directly for President and Vice-President, votes are cast every four years. When constituted, they were meant to be a council of the ablest men in the country, exercising an independent choice of the chief executive. The theory has never been fact for a moment, and since the third election not even a pretense; the institution is retained for very different reasons, and perhaps stronger ones. As a fact, the electors are only registers of the already pronounced party choice in candidates, and accept the officer under a solemn tacit pledge to act only as such. They are State bodies, and their integrity as such is

scrupulously guarded. They consist of as many members as the State's representation in both Houses of Congress; therefore a State cannot have less than three, and New York has 39. Their method of appointment is left absolutely to the State legislatures. Till about 1820-4 they were appointed direct by the legislature in most States; in 1824 popular election had superseded it in all but six, and by 1828 in all but one,—South Carolina, which retained it till 1868. The district system, which divides the State's electoral vote, has sometimes been tried as a party compromise; but at present all parties prefer the system of having all the electors on a general ticket. The State appoints the place of their meeting; Congress has fixed the time,—the second Monday in January,—to prevent a failure of any meeting through the refusal of a minority house of a legislature to join with the majority house in setting a date. The State, by act of 3 Feb. 1887, is made absolute judge of all disputes over appointment or returns; its certificate is decisive between two sets of returns, and Congress can only intervene if the State itself is unable to decide. But what is the State? This was precisely one of the questions before the Electoral Commission (q.v.), and even the new act would seem to leave room for party decision as there; and no Electoral Commission would ever be possible again. In case of vacancy in the electoral body, by death, resignation, refusal to serve, or any other cause, the State may pass laws to fill it; if it has no such law, that vote is lost, as happened in Nevada in 1864.

At their meeting, no organization is required; but it is customary to organize and elect a chairman. They then cast separate ballots (which remain the property of the State) for a President and Vice-President. In the first three elections, each simply voted (as required by the Constitution) for two persons, one a resident of a different State, without designating the office; the one with the highest vote became President, the next highest Vice-President. Obviously, as soon as parties gained firm organization, mere party loyalty would invariably produce a tie; and in 1800 Jefferson and Burr were so tied (see JEFFERSON-BURR IMBROGLIO), the resulting scandal and danger leading to the Twelfth Amendment, which obliges them to designate the office voted for. After voting, they make three lists of the persons, offices, and number of votes, and the names of the State electors certified by the "executive authority" of the State; seal them, and certify each; transmit two to the President of the Senate, one by messenger and one by mail, and deposit the third with the federal judge of the district. They have then no further functions.

On the second Wednesday in February, in the Representatives Hall and in presence of both Houses of Congress assembled, the president of the Senate opens and counts the State returns, and announces the result. In case of a tie the House decides by a majority of States, each having one vote; on a tie for Vice-President, the Senate decides in the same way. If no one candidate has a majority, the Houses decide in the same manner, choosing from the three highest candidates on the list. Thus, in 1824 John Quincy Adams was elected President by the House; in 1837 Richard M. Johnson was

ELECTRA — ELECTRICAL ENGINEERING

elected Vice-President by the Senate. But suppose the third and fourth are ties. This quite probable contingency has not been provided for, and may cause trouble. There was formerly a custom, when a State sent in conflicting electoral returns, of announcing the final result "in the alternative"—so many votes with, so many without, the disputed returns; but the Act of 1887 ends this, and it was always unworkable where the disputed votes were vital to the election. By the 22nd Joint Rule of Congress up to 1876, in case of dispute the returns from that State were thrown out, but in anticipation of the struggle over the returning boards, the Republican Senate on 20 Jan. 1876 repealed the rule.

The electoral system, despite its utter theoretic absurdity and undemocratic character, is never seriously menaced, because of its great practical utility in settling the presidential question at once on the counting of State votes. With direct popular vote, where parties are closely balanced, the result could not be known perhaps for months, and then might depend on a few thousand votes in a half-lawless district; fraud and violence would have infinite possibilities, and we should be on the verge of civil war every few years. The danger of the district system, often proposed, is the certainty of the districts being gerrymandered.

Electra, in Greek legend, the name of several personages. (1) One of the Oceanides, wife of Atlas, and mother of Dardanus by Zeus. (2) A daughter of Atlas and Pleione, who became one of the Pleiades. (3) A daughter of Agamemnon, king of Argos, who incited her brother Orestes to avenge their father's death by killing their mother, Clytemnestra. Orestes gave her in marriage to his friend, Pylades, and she became the mother of Strophius and Medon. She is the subject of a number of dramas, both ancient and modern.

Electrepeter, ē-lek-trep'e-tēr, in electricity, an instrument for changing the direction of electric currents.

Electric Action, in organ building, a mechanism in which the connection between the key-board and the pipes is made by the help of electricity. See **ORGAN**.

Electric Alarm, or **Thermostat**, an instrument used for giving an alarm when the temperature rises to a point at which the instrument completes the circuit. This is used in stoves and hothouses, to indicate excess or lack of temperature, and as a maximum thermometer alarm or fire-alarm. See **ELECTRIC SIGNALING**.

Electrical Diapason, a small instrument like a tuning fork, the vibration of which is maintained by means of electricity.

Electrical Education. See **EDUCATION, SCIENTIFIC AND TECHNICAL**; **ELECTRICAL ENGINEERING**.

Electrical Endosmosis. See **ENDOSMOSIS**.

Electrical Engineering. Electrical engineering is probably the youngest of all the professions, for it has hardly been recognized as a regular profession for more than 15 years past. As a result, the men who have reached prominence in it to-day have attained their positions from widely differing courses of preliminary training; many of them are men who started life in other lines of work and after-

ward turned to electrical pursuits on account of the sudden growth and importance of the business. In consequence of this, all methods of preliminary education are represented and their relative values can be estimated. The argument runs largely between two classes of men,—one represented by the so-called "practical man" and the other by the theoretical electrician; the graduate of the machine shop and the graduate of the university. Both of these types have attained success, but the correct answer to the argument will probably be found in a proper combination of the two types. In the past some of the most successful electrical engineers have belonged distinctly to the class of practical men with little theoretical training, but the conditions have changed. In the early days of the profession, there was little theory or predetermination of results and work was carried on largely by guesswork or by cut and dried approximations. At the present time, however, such a state of development has been reached that exactness of result is essential to success and work based upon exact theory becomes imperative. In a stationary condition of an art a man with practical experience only may become very familiar with all the existing types of apparatus and, knowing their various applications, may qualify, to an extent, as an engineer. But the extraordinarily rapid growth of the electrical arts places electrical engineering apart from all the other engineering branches, for new discoveries and theories make radical changes from year to year in the construction and operation of electrical machinery. The engineer whose education is based only upon practical experience cannot keep up with the progress and change resulting from it, and falls behind; whereas, the man with knowledge of the theory, and a mind trained by the theoretical studies and scientific reasoning, easily grasps the theory of the change and readjusts his mind to the new without difficulty or delay. Many instances can be cited of men who have been prominent as electrical engineers, who have been dropped out of place in the course of the rapid progress which has been made, on account of a lack of theoretical foundation in their knowledge. Those who have retained their positions throughout the growth of the art have done so by persistent study along theoretical lines.

In its present state electrical engineering is the most scientific of all engineering professions. A man must be to a great extent a physicist, a chemist, and a mathematician, as well as be familiar with machinery and its design, in order to be a worker in the broadest field. Many of the problems connected with other branches of engineering can be solved by common sense and by one's sense of proportion as guided by experience and by the eye. But most of the problems in electricity are invisible, so to speak, and can be understood only through their expression in the form of symbols. Probably no one will dispute to-day that the preliminary education of an electrical engineer demands a special training in those theoretical branches, mathematics, physics, chemistry, and mechanics, sufficient to train his mind into accurate methods of thought and reasoning and to supply him with the actual technical information which he will need in the practice of his profession. But theory alone is not all. The human mind is such that it works with difficulty in pure theory without a series

ELECTRICAL MANUFACTURING INTERESTS

of mental pictures to fix and co-ordinate the ideas, and the study of theory is likely to make little lasting impression unless the physical meaning of the theory is brought out by constant association with actual apparatus which demonstrates the application of the physical law. The best course of training for an electrical engineer would seem to be a broad course of education in general subjects at the preparatory school before entering college, with practical work, if possible, along lines of simple mechanics, such as carpentry, in order to train the mind into a sense of proportion and the relations of parts, which is the basis of all engineering. Next, a college course with general subjects the first year, and afterward, for the remaining years of the course, those general and theoretical subjects which have a direct bearing upon the practice of the electrical profession, such as mathematics, mechanics, physics, chemistry, theoretical electricity, and magnetism and thermodynamics. This should be supplemented by actual daily practical work with machinery operating by the principles covered by the theory studied and demonstrating all the phenomena incident to the theory. After graduation an apprentice course should be pursued in some large electrical manufacturing establishment where the commercial relations of the knowledge acquired in college can be clearly set forth. Large machines can be operated which are not available at a college and experience in the installation of large plants can be obtained, and experience gained in the designing departments where all kinds of commercial apparatus are laid out.

After a few years of this training, specialization may begin along the lines selected for the life work but preferably not before. A man makes a mistake to consider himself a qualified electrical engineer after he has been graduated from college, for he is not one. His mind has been trained into a condition where he can readily absorb the principles of the electrical profession, but that is all, and the subsequent apprentice training is as important as the college course, in order to acquire the broad viewpoint from which to make the correct start in the direction in which a man is best fitted. It perhaps means a smaller income the year after graduation from college, but it means much more at the end of five years. But theory and practice are not the only elements necessary for the successful engineer. There are many qualities required in common with other professions; executive ability, business knowledge, presence of mind and ability to handle men, nerve and resourcefulness in handling machinery in times of emergency, are all necessary to the successful engineer. These elements cannot be ac-

quired in the study of theory and practice alone, and many men who have stood high in their college courses have failed afterward in the practice of their profession because of a lack of these qualities. The study of chemistry becomes more and more important as the profession advances, for the branch of electro-chemistry is rapidly developing and is likely to become one of the largest fields in the application of electrical science. And almost above all comes a training in the English language. No man who cannot express himself clearly and concisely in writing or in conversation can hope to attain a prominent position in his profession. The education of an electrical engineer, however, must never be considered as completed. The art advances so rapidly that constant study is necessary, even to keep up with the progress of the times. But an electrical engineer should be willing to do more than this. He should study to keep ahead of progress and do his share toward the instruction of others.

H. W. BUCK,
Electrical Engineer.

Electrical Manufacturing Interests. A few pieces of experimental electrical apparatus were the entire product of electrical machinery between 1800 and 1825 and constituted the bases from which later inventions and developments dated. Only within the last 50 years when the correlation of electricity and magnetism was fairly understood, and the ability to turn mechanical energy into current fully perceived, did there come in quick succession telegraphy, electroplating, electric lighting, telephony, electric power, electric traction, electric heating, forging, welding, and cooling and the electric extraction of minerals and precious metals. In the promise of the future, electricity now associated with intense and crowded city life is likely to be the agency chiefly to be relied upon in the closer knitting together of city and country, the increasing of facilities for commerce, and the diffusion of information throughout remote districts.

The telegraph, representing a pioneer electrical development, has not yet attained the magnitude of maturity. Inclusive of allied and similar services to the public, the telegraph system of the United States reaches a capitalization of about \$250,000,000, of which the Western Union and Postal lines may be credited with more than one half. The condition of the telegraph industry in the United States and Europe is portrayed in the following figures:

The telegraph systems of Europe are all conducted by the government of each country, and are almost bankrupt, as compared with

STATISTICS OF EUROPEAN AND AMERICAN TELEGRAPHS.

DIVISIONS	Population	Miles of Line	Miles of Wire	Offices	Messages	Receipts	Cost of Maintenance	Area in Square Miles
Europe Including Russia, Egypt, Asia, Algeria, etc.	393,178,871	425,600	1,585,267	76,764	258,584,166	47,542,222	25,393,342	10,886,619

ELECTRICAL MANUFACTURING INTERESTS

the economic success of the private enterprises in America. It may be added that the great and small steam railroads in America also maintain their own telegraph service. That of the New York Central costs \$300,000 a year.

As for telephony, the advent of Prof. Bell's telephone in 1876 found capital quite averse to assuming any risk in it, and even in 1879 the Western Union Telegraph Company surrendered all its telephonic work to the American Bell Telephone Company, on condition of being paid for a term of years 20 per cent commission on the receipts in royalties from the telephone, which brought about \$7,000,000 into the Western Union treasury. But the telephone has meantime gained ground so enormously that some observers believe the effectual supersession of the telegraph to be well in sight. The American people now exchange yearly not far from 3,000,000,000 telephonic talks; that is, they use the telephone 30 times as much as they do the telegraph, at infinitely less cost.

The capitalized value of the telephone business of the United States is estimated between \$400,000,000 and \$500,000,000; of which about \$125,000,000 represented in 1901 the American Telephone & Telegraph Company (Bell system), then operating through about two score sub-companies which had expended nearly \$170,000,000 in building up a system of 1,348 exchanges with 800,000 subscribers and handled 1,825,000,000 exchange connections a year. Owing to the expiration of the fundamental telephone patents, however, about 5,000 "independent" local telephone exchanges, outside the Bell system, and using the apparatus of as many as three score manufacturers, sprang into being. They probably have not less than 750,000 subscribers. A large amount of "interior" telephone work has been done of late years for factories, mills, hotels, and apartment houses. Farmers have particularly benefited by the "independent" movement, and have largely participated in it on the co-operative plan. As compared with Europe, the United States show a remarkable preponderance in the use of the telephone. As against 1,500,000 subscribers in this country, Germany has 229,391 stations; Great Britain, 171,660; Sweden, 73,500; France, 59,927; Switzerland, 38,864; Austria, 32,255; Norway, 29,446; Russia, 31,376. It is often claimed that service is cheaper in Europe than here. Superficially considered, this may be true, but it is quite erroneous when the quality of service is taken into account. Under the present competitive conditions, telephony is being remarkably cheapened in America, and the industry is growing at a rate beyond all parallel. See TELEPHONE.

Fire-alarm telegraphs have been an important item in this field of manufacture, and the Gamewell system is perhaps the best known. At the present time about 800 cities have fire-alarm telegraph systems. Every city has now its police telegraph also, many combining with it a telephonic patrol system that brings a squad to any point within five minutes after the call is sent in. The district messenger system has become familiar in most American cities, as an auxiliary to the telegraph. In New York the average number of boys employed for this work was recently estimated at 1,200, who ran some 2,500,000 errands in a year. See ELECTRIC SIGNALING.

As an offset, perhaps, to the European pre-

eminence in the one department of submarine telegraphy, we may turn to the generous figures of the growth of electric lighting in the United States. There are about 3,000 local electric-light companies here, and some 500 municipal plants. The investment in central stations and isolated plants is placed at \$1,000,000,000. Of isolated plants for arc or incandescent lighting in mills, mines, stores, halls, docks, etc., the number in the United States has reached not less than 10,000; there were in 1893 no fewer than 3,500 such isolated incandescent plants, which had a capacity of 1,500,000 lamps. All this is the outcome of the inventions of Edison, Brush, Elihu Thomson, Weston, Wood, Hochhausen, and, in the new era just beginning, Nikola Tesla, Stanley, Bradley, and Steinmetz. At one time some 40 or 50 manufacturing companies competed for the sale of the plant; but the art has in many respects become specialized.

There are now in the United States about 500,000 arc lights and perhaps not less than 30,000,000 incandescent, large numbers of the arcs being of the "enclosed" type, a comparatively recent introduction. Of late years there has been a steady growth in the use of electric motors deriving current from central station circuits, and using about \$10,000,000 worth of current a year. Hundreds of industrial establishments have power-plants of their own, and thousands of motors, replacing steam and other engines. Within the past few years, electric power transmission also has grown wonderfully, and the investment in that field alone is estimated at \$100,000,000. Many transmission plants are associated with electric lighting and street railway enterprises; others are for mining operations or for industrial purposes in general. The most striking plants in the world for power transmission are found on the Pacific slope. One of them, that of the Bay Counties Company in California, is now sending power in large quantities electrically from Colgate to San José, a distance of 184 miles. One of its circuits crosses the Strait of Carqueinez in a single span 4,427 feet long. On one section of its line, 142 miles in length, a pressure of 40,000 volts is used, and this is now being increased to 60,000 volts. The great utilization of Niagara electrically is familiar to all. There are probably between 600 and 700 electrical manufacturing concerns in the United States, varying greatly in size. As to light and power, one company making apparatus for these uses alone had sales in 1900 of \$28,783,000, and more than 12,000 employees working in three main factories, which have nearly 2,500,000 square feet of floor space.

Electric railroading was the object of much experiment. The work of Thomas Davenport, a Vermont blacksmith, in the fifties, embodied many of the elements familiar in the street-railway of to-day; but no progress was made, because the primary battery was then the sole source of current. Within the last 15 years the electric railway industry was thoroughly established through the inventions of Sprague, Van Depoell, Henry, Daft, Field, and others. In 1887 there were only 13 small roads. With the year ending June 1901 the trolley systems in the United States reached the total of 905, with 19,314 miles of track, 55,000 cars, and a capitalization of fully \$1,750,000,000, which in spite of frequent inflation has a notable dividend-earning capacity, rarely

ELECTRICAL MANUFACTURING INTERESTS

falling below 6 per cent for the bonds, and the common stock receiving as much. The ability of electricity to increase the traffic of a street-railway has hardly ever been less than 40 per cent in the year of its adoption, and has frequently exceeded 100 per cent. The annual increase in the number of electric railways in America long equaled the entire number in Europe, averaging about 100. This increase represents a purchase of some \$100,000,000 worth of rails, cars, motors, wire, engines, boilers, poles, etc. This particular industry has endless aspects. In New York, Washington, and Chicago, underground trolley-conduit roads are being adopted instead of the overhead trolley type, with great success. In Chicago, at the World's Fair, an elevated electric road carried 8,000,000 passengers, and there is now a similar road in regular operation in that city. In New York the tunnel electric-railway system, to cost the metropolitan taxpayers \$50,000,000, is on the plan so successful for some years past in London, and the Manhattan Elevated system in New York is spending millions of dollars on an electrical equipment for all its cars. More interesting still is the inter-urban extension of the trolley system. Some of these country roads are hundreds of miles in length. The competition of these roads and the regular street trolley railways with steam railroads has begun to revolutionize the latter, because 10 miles for 5 cents is an ordinary car trip, and the steam train needs 10 cents for 5 miles for its maintenance. On some steam roads the suburban travel has been practically wiped out, and a great many schedules have been abandoned. To meet this serious condition of affairs the Pennsylvania, and the New York, New Haven & Hartford railroads, among others, have adopted electricity for some of their branches with marked success; and the intention is to carry this change much farther at once, a marked instance being the projected use of electricity in bringing trains on the New York Central system through the outlying parts of the city into the Grand Central Depot. Additional to this is the use of heavy 1,500 horsepower electric locomotives by the Baltimore & Ohio Railroad Company for freight haulage in its Baltimore tunnel. These locomotives haul trains of 1,400 tons, and make, when necessary, a speed of 60 miles an hour. In short, the steam railroad system is at the point of a new departure, and is everywhere being prepared for the greater utilization of electricity.

An art allied to electric locomotion is that of electric navigation. At the World's Fair in Chicago in 1893, 1,003,500 passengers were carried on the lagoons by a fleet of 50 electric launches; and these boats, scattered all over the country, have become nuclei for a number of smaller fleets employed by trolley railways, park boards, police departments, and private owners. These boats are operated by means of storage batteries, charged from time to time, and able to run them continuously for 40 or 50 miles. A boat of such a character, 35 feet in length and 6 to 8 feet beam, making 10 to 12 miles an hour, is obtainable complete for about \$1,600.

The storage battery has been more successful afloat than in street-car propulsion, but is now rapidly coming into use for isolated plants, street railways and central stations, chiefly as a reservoir of current when the machinery is not in

operation. During 1900, one storage-battery company filled orders for \$3,500,000 of plates, and shipped 11,688,151 pounds of plate for various types of cells. It is becoming the practice, also, to equip fire-alarm departments with storage batteries in place of the old primary batteries. See ELECTRIC STORAGE BATTERY.

Electric mining is one of the latest of the industries to be developed by the electrical engineer, and bids fair to surpass the electric railway in magnitude. The demand for apparatus in it is estimated to have passed already \$100,000,000 for hoists, crushers, drills, pumps, ventilators, cars, etc. The adoption of this machinery, furnished with current from dynamos driven by water-power, has enabled scores of mines to pay expenses that were unable to do so with fuel as high as \$15 a ton. Some of these plants are being operated at altitudes of 12,000 feet above sea-level, and exemplify the beauties of long-distance electrical power transmission, in itself now a separate field of endeavor.

A recent development of traction work has been found in "telpherage," the invention of the English scientist, Fleeming Jenkin. Small electric motors travel along aerial wires, hauling loads after them in receptacles suspended below them. In this manner tracks are dispensed with, lines of transportation can be run across rivers, farms, plantations, etc., and produce carried to market, or supplies distributed from a common centre. The system is analogous to that of cable haulage, already abandoned in street-car work. The handy little motor is fed with current from the wire, which is both conductor of electricity and a track. Several telpherage plants have recently been installed, one of them being sent to Cuba. But for the fact that our own markets have had so large a capacity of consumption, an enormous export trade in American electrical apparatus would have grown up long ago. As it is, the demand from foreign countries in certain lines is already respectable. American electrical apparatus finds a market throughout the entire globe, not only in such new civilizations as Japan, China, and Korea, but in England, and Europe. At the present moment, London has in operation a most successful underground road, equipped with American apparatus, and C. T. Yerkes, an American, is reorganizing, electrically, the old Metropolitan underground system. Indeed, if the remark of Emerson be true, that steam is half an Englishman, we may with equal felicity assert that electricity is nine tenths an American.

The above are to-day the main lines of American electrical manufacturing and supply of current, reaching toward a capital of \$3,000,000,000; but they are not all, and they draw their material from many subsidiary industries. The electric refining of metals is a growing department, in which millions are invested annually. The returns of 1899-1900 show that in copper treatment alone, some 200,000 tons of "electrolyte" are now produced annually in the United States, with 170,000 ounces of gold, and 21,000,000 ounces of silver as by-products. Electricity is also being used for the production of large quantities of aluminum, graphite, carborundum, and calcium carbide. There were in 1895, 392 electroplating establishments in the United States, with a capital of \$38,000,000, employing 2,700 hands; and there were also no fewer than 300 electrotyping

ELECTRICAL MORTAR—ELECTRIC ALTERNATING CURRENTS

firms, besides large numbers of etching and jewelry houses using current in their work. The insulated wire and cable factories number a dozen. Their output mounts into countless millions of feet of wire annually, while the practice of running interior wires through tubes has necessitated the production of some 45,000,000 feet of insulated conduit annually. Merely placing wires underground is estimated to have required \$150,000,000 for cables and subways. Every hotel in the country has its annunciator system, and every private residence of any pretension has at least its electric bells. In medicine, electrotherapy is so well recognized that a score of large manufacturers are busy turning out galvanic and faradic apparatus for practitioners of all schools. The production of disinfectants electrically has assumed large proportions, and their use is growing. The place of electricity in education may be gauged by the fact that more than 1,500 students take up electrical engineering in a single year as a special study at leading colleges. It is seen clearly to-day that the future of all the electrical arts depends upon a reduction in the cost of current, and to this end Nikola Tesla (q.v.) has suggested many novel and ingenious schemes. Others are working at the problem of obtaining electricity directly from heat; and the future seems big with promise.

T. C. MARTIN,

Editor The Electrical Engineer.

Electrical Mortar, a small mortar in which is placed a discharge to take place between two bodies of contrary electricities. The discharge is so instant as to expel a light ball placed in the mouth of the mortar.

Electric Alternating Currents. A loop of wire, revolving between two magnet poles of opposite polarity, is the simplest form of an alternating current generator. The direction of induced electromotive force in the two halves of the loop, which cut the magnetic flux in opposite directions, is such that the combined electromotive force at the terminals is double that of either revolving conductor alone. This induced electromotive force is proportional to the rate of cutting the magnetic lines, and therefore to the sine of the angle by which the plane of the coil differs from the plane midway between the poles and normal to the magnetic flux. At its zero position, or when the planes coincide, the coil is cutting no lines of force and we have $\sin \alpha = 0$. The electromotive force, however, grows as we depart from this zero position, assuming uniform speed, until, when 90° is reached the rate of cutting of the lines becomes a maximum, $\sin 90^\circ = 1$. Passing on, the electromotive force dies away until 180° is reached, when the value again is zero. From this to 270° we have an increasing electromotive force, but of opposite polarity and at the end of the revolution, or 360° , again reach zero. Thus we have in one revolution in a two-pole field, two waves of pressure of the same form but of opposite sign. The one is called the positive wave and the other the negative. One such revolution, or one positive wave and one negative wave, constitute what is called a cycle, or period. The periodicity of modern alternators varies from 133 cycles to 15 cycles per second. The great majority of systems have a frequency between $60\sim$ and $25\sim$. Both of these frequencies

are standard practice in this country, and the values between are chosen for special cases. Owing to the high frequency of commercial systems, alternators are built with more than one pair of poles, in order to keep the revolving speed within reasonable limits.

Average and Effective Values.—If we plot the values of the instantaneous pressures as ordinates, with time as abscissa we have a correct representation of the generation of alternating currents, and the shape of the wave. When the total number of lines cut per revolution by a coil revolving at constant speed remains the same, the average induced electromotive force remains constant, regardless of the distribution of the magnetic flux. The effective value, however, the value read by the meter and the value which corresponds in its heating effect to the direct current value, is not independent of this distribution.

The Place of Alternating Current Systems.—The direct current for the railway at 550 volts, and for the lighting and power systems of the densely populated centres of our large cities in the Edison three-wire system 110 to 220 volts, seems to have become standard practice. Nevertheless the low radius of distribution without excessive cost of copper, even in the 550 volt railway system with a grounded return, makes necessary a great multiplicity of moderate sized or small plants, operating at low efficiency. It is here that the alternating current comes to the front. While commutators (q.v.) can be built for collecting direct current at 1,000 volts, alternators (q.v.) can be built for 12,000 volts and step-up transformers (q.v.) of high economy are quite possible at 75,000 to 100,000 volts. Remembering that the copper cost is inversely as the square of the voltage, the great possibilities of the alternating current systems are at once seen.

Energy from Waterfalls.—Electrical energy from waterfalls that a few years ago were, at most, points of scenic interest, is now supplied to more than 50 cities in North America. The line from the 15,000 H. P. plant at Colgate, California, to San Francisco, by way of Mission San José, where it is supplied with additional power, has a length of 220 miles, and is the longest transmission of electrical energy in the world. The line between the 13,300 H. P. plant at Electra and San Francisco is 154 miles. In the east, the line between Shawinigan Falls and Montreal covers a distance of 85 miles. The great 105,000 H. P. plant at Niagara regularly supplies Buffalo with 16,000 H. P. of energy for railways and lighting.

The Alternator.—Small alternators and those of moderate potential usually collect their current from insulated rings mounted on the shaft and connected to the ends of the armature winding. Through brushes, the current is taken to the external circuit. In some machines a rectifier is added for supplying sufficient unidirectional current to produce the necessary additional field to overcome the drop due to increase of load. All commercial alternators are supplied with an exciter, or direct current dynamo, whose function is to supply current to the field windings. The field spools are usually connected in series. The amount of current thus necessary, on a full non-inductive load varies from $1\frac{1}{2}$ to 3 per cent of the total output of the alternator. Owing to the difficulty of collecting large currents by means of brushes and of preserving good insulation between the rings and

ELECTRIC ALTERNATING CURRENTS

shaft, the revolving field type of machine is now used in almost all large installations, the field current from the exciter being supplied through cast-iron rings mounted on the shaft, or in the case of the inductor type, consisting of an annular ring surrounding the inductor or revolving element, which consists of laminated iron poles suitably spaced and keyed to the shaft. The windings being stationary, there are no moving connections, either for the field current or the main current of the machine. In either type the alternating current is taken from the terminals of the windings, usually at the bottom of the frame.

Polyphase Machines.—If two armatures, of the same number of turns each, be connected to the shaft at 90° from each other, and revolved in a bi-polar field, and each terminal be joined to a collector ring, we have two separate electromotive forces differing in phase by 90° or a two-phase machine. With 120° phase difference and three sets of armatures we have a three-phase winding. By properly interconnecting the three circuits, we may use but three wires for transmission, or four, in accordance with the system used. The construction of multiphase machines is similar to that of the single-phase type, excepting that in the former we have as many armatures, series connected, as there are phases.

In the two-phase three-wire system, the wire from the common junctions of the phases carries 1.414 times the current of the outer wires. The electromotive force between the outer wires is also $\sqrt{2}E$, when E is the electromotive force per phase, or between either outer wire and the common return. When this system is used it is important that the load be carefully balanced on the phases and that the power factor be kept as high as possible in order to keep the voltage on the phases nearly alike at the receiving end. Single phase motors or lamps may be connected to either or both phases, but it is very important that no load be connected between the outer wires, as the effect is to badly unbalance the voltages on the different phases.

In the three-phase star connected system the line voltage is $\sqrt{3}=1.732$ times the voltage on the coils of the machine, or the machine voltage, which is the pressure between any one of the three line connections and the common neutral. The line current in this system is the current that flows through any one of the machine windings. In the delta connection, the line voltage is the same as the voltage across any phase of the machine, while the line current, being the resultant of two currents, is $\sqrt{3}=1.732$ times the current flowing through any phase of the machine.

Energy Polyphase.—In a two-phase circuit, whether three or four wire, the energy flowing is the sum of the products of each phase current by the phase pressure. Two wattmeters are used. In the three-phase system when E =volts between lines; I =amperes on lines; W =total watts output of machine,—then, whether the connection be star or delta, the total

output is $\frac{3E \times I}{\sqrt{3}}=1.732 EI$, always supposing the system be balanced. Thus the output of the machine is not changed by changing the connections from star to delta. In the balanced three-phase system, one wattmeter will register

the total output if its constant be multiplied by 1.732. Two wattmeters are usually employed.

Regulation of Alternators.—The regulation of modern alternators varies from 5 to 6 per cent, which means that in case the full, non-inductive load of an alternator be taken off, the speed and excitation being kept constant, the terminal pressure will rise by an amount corresponding to from 5 per cent to 6 per cent of its full load voltage. Close regulation means a much better voltage-regulation on the system and stronger synchronizing power. A certain amount of armature reaction is necessary to avoid large cross currents on changing the field of one or more machines operating in parallel, in the attempt to preserve the same terminal voltage. The efficiency of large alternators is about 96 per cent to 97 per cent.

Frequency.—In regard to the frequency best adapted to transmission work, or to local distribution, various factors enter into the problem. At 60~ both arc and incandescent lamps can be operated satisfactorily. The transformers are smaller and cheaper than at 25~ and motors are very satisfactory both as to low first cost, range of speed, and good starting torque (q.v.). Frequencies over 60~ have been abandoned. The line drop, due to reaction increases with the frequency, a change of frequency from 25~ to 125~ would, on the same line, more than double the line drop. While as a rule 60~ apparatus is cheaper than that for 25~ yet the increase in polar speed often becomes difficult without increasing the number of poles to an undesirable extent, which, in 60~ apparatus, may be sufficient to make the parallel operation of low speed direct-connected alternators quite difficult.

Self-induction.—When a current is introduced into a circuit a magnetic field is produced, surrounding the conductor, the rise of which causes a counter electromotive force. This electromotive force is called the electromotive force of self-induction. The effect of self-induction upon electric currents is directly comparable to the effect of inertia on a material body. It is that quality that tends to hinder the introduction, variation, or extinction of the current in a circuit. As this effect is greatest at times of most rapid change of magnetism set up by the current, in alternating current circuits, it becomes a maximum when the inducing current is passing through zero, and therefore, the counter electromotive force of self-induction lags 90° behind the current in the circuit. It also follows the sine curve provided the current flowing is sinusoidal.

In a circuit containing several impedances in series, the joint impedance is not the sum of the individual impedances, but is obtained by taking the square root of the total added reactances squared plus the total added resistances, squared, or Impedance =

$\sqrt{(R_1 + R_2 + R_3)^2 + (2\pi f L_1 + 2\pi f L_2 + 2\pi f L_3)^2}$
The joint impedance of several impedances in parallel is found as follows. Construct a parallelogram from the reciprocals of two of the impedances, each expressed in its proper phase relation. The direction of the diagonal will give the phase of the resultant impedance, and its reciprocal amount will give the reciprocal of its length. For more than two, the method of the polygon of forces is applied.

INTERIOR VIEWS IN THE WORKS OF THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY.

ELECTRIC ALTERNATING CURRENTS

The effect of self-induction varies with the frequency of the current supplied, and as the square of the number of turns in a circuit. The self-induction in the armature of an alternator has two effects. The first is to produce a lagging current and thus lower the terminal voltage, and the second is a demagnetizing effect. The current is thrown into such a phase that it produces lines of force directly opposed to the field and thus lowers the voltage by reducing the total flux. The effect of armature reaction depends upon whether the current is leading or lagging in phase. A lagging current lowers the voltage of an alternator and a leading current raises it.

Capacity.—All insulated conductors have the quality of being able to hold stored on their surface, a certain quantity of static electricity, and are thus condensers. The charging and discharging of an alternating current circuit causes the current to flow from the generator into the line and then back into the generator again, with the frequency of the alternator, in order to keep up the static potential on the line. As this charging current is greatest when the rate of change of electromotive force is greatest, a sinusoidal wave of capacity electromotive force with 90° difference in phase from the machine electromotive force is produced. This leads the active electromotive force by 90° and is thus 180° or opposite to the electromotive force of self-induction. If we have a circuit in which the electromotive force of self-induction is just equal to the capacity electromotive force, and these two parts of the circuit are in series, the effect of both is neutralized and we have, as in direct currents, $W = E \times C$.

The Transformer.—The one piece of apparatus that, more than all else has made possible the electrical transmissions of energy to long distances, is the transformer. This is the apparatus that receives in one set of coils the dangerous potential of the line and transforms it into whatever potential is desired for lights or motors, which are supplied from an entirely separate winding. The transformer consists of a magnetic circuit of laminated iron or mild steel interlinked with two electric circuits, one, the primary, receiving electrical energy and the other, the secondary, delivering it to the consumer. The effect of the iron is to make as many as possible of the lines of force set up by the primary current cut the secondary winding and there set up an electromotive force of the same frequency, but different voltage.

Not only does the transformer make possible the transformation of voltages, but it also permits of changing from one system to another. Thus a single-phase primary may supply a three-wire Edison system, of course, with alternating current. A two-phase system can be changed to a three-phase or *vice versa*; a four-wire two-phase may make a three-wire two-phase, and many other useful combinations be effected. The Scott connection for changing two-phase to three-phase, or the opposite, uses but two transformers. One has a ratio of, say, 10 to 1, with a tap at the middle of its secondary coil. The other must then have a ratio of 10 to .867 = 10 to $\frac{\sqrt{3}}{2}$. One terminal of the secondary of this transformer is connected to the middle of the other secondary, and the remaining free ends

of both secondaries form the three terminals of a three-phase circuit. The value $\frac{\sqrt{3}}{2}$ is the altitude of an equilateral triangle of which the base is unity, and thus we may consider the current to be taken from the corners of an equilateral triangle, which represent, in phase and potential difference, a true three-phase system. The current in the transformer of secondary, .867 being the resultant of the other two phases, is greater than under normal two-phase conditions; and, therefore, the windings must have about 15 per cent more copper. If two similar transformers are used the secondary of each has taps giving 50 per cent and 86.7 per cent of full voltage. In many large installations, notably at Niagara Falls, we find two-phase generators feeding three-phase lines through Scott connected step-up transformers. In small systems standard transformers may be used having ratios of 10 to 1 and 9 to 1 respectively, and the results will be quite satisfactory.

The Induction Motor.—Acting upon the well-known fact that a copper disk could be made to revolve by rotating a horseshoe magnet so that the lines of force cut the disk, Ferraris, Tesla, Dobrowolsky, and others have developed the present type of induction motor. The credit for the first commercial application of the rotating field caused by currents of displaced phase probably belongs to Tesla. At the present day the value of these discoveries in the transmission and distribution of power can hardly be estimated. The induction motor is somewhat similar to the direct-current shunt motor. Both motors have field and armature windings. In both cases, also, the field is connected directly across the mains. In the shunt motor the armature current is supplied through brushes and a commutator to the windings, while in the induction motor the armature current is an indirect current, the field acting as the primary of a transformer of which the armature is the secondary. In both motors the efficiency is inversely proportional to the armature resistance, as is also the speed regulation of the motors. The less the armature resistance the higher the efficiency and the closer the regulation of speed between no load and full load. In practice, either element may be the one to revolve. The rotation is produced by the reaction of the armature, or indirect current, on the revolving magnetic field, which results in dragging the moving element around in order to keep up with the field flux, as it passes around the face of the primary windings. This field, being the resultant of two or more alternating fields of different phases, rotates with the polar frequency of supplied voltage. The secondary winding is made up of copper bars set in slots in a laminated iron core and running across the armature parallel with the axis of rotation. This separating of the old copper disk into narrow bars constrains the current to flow into the best direction for producing torque and avoids the waste of the unconstrained Foucault currents in the Arago disk, and thus makes the motor much more efficient. Sometimes the secondary windings are joined to heavy short circuiting rings, at both ends resulting in the squirrel-cage type of motor; and in other cases the secondary windings are taken out through collector rings, if the secondary be the rotating element, and

ELECTRIC ALTERNATING CURRENTS

starting resistances are inserted in series to lessen the reaction due to excessive starting current and thus improve the starting torque. When up to speed these resistances are cut out and the terminals short circuited as in the squirrel-cage type.

The Asynchronous Generator.—If the motor be driven by power from an outside source up to true synchronism, no current will flow in the secondary, and the primary current or field current will be wholly made up of the wattless exciting current, just as in a transformer at no load. The slip, or amount by which the motor speed at full load differs from synchronous speed may be as little as 2 to 2½ per cent of the speed of synchronism in large motors, and in small motors may be 5 per cent or more. If the motor above mentioned be forced above synchronism the motor becomes a generator, provided the connection to the mains is left closed, and when a negative slip of the same amount as full load slip as a motor is reached, the generator will be giving out its full output at the same frequency as the exciting circuit. The possibilities of this system are interesting.

The Synchronous Motor.—The synchronous motor is merely an alternating current generator of special design. Both motors and alternators have a direct current field and an alternating current armature. The operation of a synchronous motor, when once brought up to speed and thrown into circuit is the same as that of an alternator in parallel with one or more alternators. When the back pressure of the motor is equal and directly opposed to that of the line no current can flow. The friction, however, causes the revolving element to lag slightly behind the line pressure, and a current is driven through the motor by the generator. This current increases directly with the lag behind the central-phase position caused by increased load. A good synchronous motor, while always revolving at the same polar speed as the alternator supplying the line current will carry a load of five or six times full load before it breaks out of step, and becomes practically a short circuit on the system. The current which passes through such a motor on short circuit, while held down by the inductance of the windings, is yet sufficient to rapidly damage the insulation if not cut off. The great advantage of the synchronous over the induction type of motor is that the power factor can be raised or lowered at will. By raising the field strength of a synchronous motor the current taken by the motor may be made leading and hence help keep up the line voltage on a heavy inductive load. This is of the greatest importance in practice. It is good practice to set the field strength for a good power factor at full load. At light loads the motor is assisting the generator to maintain the required pressure. Another advantage of the synchronous motor is that it can easily be built for very high voltage, especially the revolving field type,—a 12,000 volt motor is not at all unusual practice. Thus the use of transformers may be dispensed with.

The Rotary Converter.—The rotary converter is a specially designed direct-current generator provided, at proper points in the winding with taps to collector rings, from which, if the machine is run as a motor from the direct current side, an alternating current may be taken. Usually the alternating current is taken from the secondaries of suitable transformers and supplied to the rings, driving the rotary as a syn-

chronous motor, the direct current being taken from the brushes on the commutator. As the reaction of the incoming alternating current about balances that caused by the outgoing direct current, the armature reaction of such a machine is very small and the brushes can be always kept in one fixed position. If the taps from the armature are taken off at points differing 180° from each other, electrically, we have a single-phase rotary. If connections are made 90° apart we have a two-phase rotary, using four collector rings. Taking 120° around the armature for our taps we have a three-phase rotary, using three collector rings. By adding to the number of taps and therefore to the number of rings we may have a six-phase rotary. The output of a rotary is greater than its output as a direct current generator, chiefly, on account of the absence of armature reaction and because at certain positions the current flows straight from collector ring to commutator and thus avoids the loss due to heating. The rotary converter, with its step-down transformer, is the most efficient means we now have of transforming the high tension polyphase currents of our large central stations to direct current for the Edison system, and for railway purposes. This piece of apparatus is wound either shunt or compound, in accordance with the use for which it is intended. As in the case of the synchronous motor, the rotary is a valuable help to the central station by running at a very high power factor. By over-exciting the fields the current taken by the rotary becomes leading and helps to hold up the voltage of the central station in case of a heavy load of induction motors by means of the armature reaction of the generators. Owing to very high commutator speeds at the higher frequencies, rotaries are not much used on frequencies above 60~. At this frequency they operate satisfactorily. At lower frequencies, however, rotaries are at their best, and will stand enormous overloads, sudden changes in load and other disturbances with perfect satisfaction. The voltage of the direct current end of a rotary is that of the peak of the sine wave of the alternating pressure, and thus a voltmeter across the collector rings

would read $\frac{E}{\sqrt{2}}$ where E is the direct current

electromotive force in single and two-phase rotaries. In the three-phase system the ratio between the alternating current pressure and the direct current at the commutator brushes is $\sqrt{3}$

$\frac{E}{2\sqrt{2}} = 613$. Thus in the Edison system operat-

ing at 250 volts we should have to transform down to $250 \times .613 = 153$ volts at the secondary of the transformers. While rotaries can be started up without field, from the alternating current side, it is not good practice, excepting in certain special cases. Generally they are started up exactly like a shunt motor, synchronized and then thrown upon the alternating current line. When a rotary is started up from the alternating current side, on closing the field switch it is impossible to tell what the polarity will be. Rotaries operate in parallel with perfect satisfaction, as a rule, on both the alternating current and the direct current sides. The storage battery is always used in a large rotary

ELECTRICAL UNITS—ELECTRIC BLUE-PRINT MAKING

installation to insure against any possible contingencies. On compound rotaries the equalizer must be used, just as in the case of direct-current compound generators. See **ELECTRIC DIRECT CURRENT**.

Electrical Units. See **UNITS**.

Electric Annealing, annealing by the heat produced by the passage of the electric current through the body to be annealed. In 1893 an American electrician discovered that a bar of iron immersed in a solution of sulphuric acid and cold water could be easily fused by the application of a strong electric current. The mode of procedure is as follows: The vessel employed is made of glass or porcelain, provided with a sheet-lead electrode connected to the positive pole of a continuous-current generator, and contains a mixture of sulphuric acid and water. A flexible cable from the negative pole is connected to a strong pair of pliers with insulated handles. Taking a piece of metal of any kind and immersing it in the acidulated water, the liquid is seen to boil near the iron rod or plate, which latter is rapidly heated, and brought to a dazzling whiteness in a few seconds, and soon begins to melt. The heating is produced so quickly that neither the liquid nor the body of the metal rod has time to become hot. So rapid an evolution of heat necessarily means a tremendously high temperature. In a very short time a temperature of 7,000° F. has been developed, which is proved by using a carbon rod instead of a metal one, when in a few moments amorphous carbon fragments are seen dropping off. With strong currents the enormously high temperature of 14,000° F., or nearly five times hotter than molten iron, has been produced.

Electric Annunciator, a form of annunciator, used in private houses and hotels. See **ELECTRIC SIGNALING**.

Electric Arc, a brilliant luminous arc produced when an electric current is passed between two pointed carbon rods placed a short distance apart. The rods are first put in contact so as to allow the current to start. On their being separated slightly the arc is formed, and once formed it serves as a conductor whereby the flow of current is maintained. The temperature of the electric arc is the highest which has been obtained by artificial means. See **ELECTRIC LIGHTING**.

Electric Aura, a current or breeze of electrified air employed as a mild stimulant in electrifying delicate parts, as the eye.

Electric Automatic Fire-alarm. See **ELECTRIC SIGNALING**.

Electric Automobiles. See **AUTOMOBILES**; **TRACTION**, **ELECTRICAL**.

Electric Balance, an instrument for measuring the attractive or repulsive forces of electrified bodies. A form of electrometre, consisting of a graduated arc supported by a projecting plate of brass which is attached to the perpendicular column. A wheel, the axis of which is supported on anti-friction rollers, and is concentric with that of the graduated arc, carries an index. Over this wheel, in a groove on its circumference, passes a line, to one end of which is attached a light ball of gilt wood, and to the

other a float, which consists of a glass tube about one fifth of an inch in diameter, terminating in a small bulb, so weighted that the index may point to the centre of the graduated arc. The difference between the weights of the float when in and out of water is known, and the diameter of the wheel carrying the index is such, that a certain amount of rise or fall of the float causes the index to move over a certain number of graduations on the arc. See **ELECTROMETER**.

Electric Bath, in electro-plating, the solution used for depositing metal as contained in a vat or tank. In electro-therapeutics, a bath with suitable arrangements, electrodes, and connections, for treating patients with electricity. See **ELECTROPLATING**; **ELECTRO-THERAPEUTICS**.

Electric Batteries. See **BATTERY**; **ELECTRICITY**; **ELECTRIC STORAGE BATTERIES**; **ELECTRIC VOLTAIC BATTERIES**; **PRIMARY BATTERIES**.

Electric Bell. (1) **Magnetic or dynamic:** Two electro-magnets, parallel and in series, having at their extremity a vibrating armature in close proximity pivoted between them; fixed to this armature is a clapper vibrating between two gongs. The current passes through the fields, magnetizing the cores, and in generating an alternating current vibrates the armature and rings the bell. (2) **Battery-bell:** A single coil or bobbin of wire, wound around an iron core; a vibratory armature, pivoted at one end, and passing at a right angle by the core of the bobbin; at the other end of the armature is a clapper, a gong situated close to the clapper. A delicate spring is attached to the vibratory armature near the clapper, which, while the current is passing, operates against a set-screw placed for the purpose. The current passing through the bobbin to the set-screw magnetizing the core, attracts the armature which in turn is repelled, the spring working against the screw. These alternate attractions and repulsions of the armature vibrate the clapper and ring the bell. See **BATTERY**.

Electric Blue-Print Making, a modern process of wholesale photographic printing, by the aid of machinery, the electric light, and the blue-print (q.v.). One of the best machines, shown in the accompanying sectional cut, is

Cross-section of Blue-printing Machine.

continuous in its operation, and is fed by the operator with great lengths of tracings and blue

ELECTRIC BOAT—ELECTRIC DENSITY

paper in much the same manner as the wash-woman feeds the wet clothes into a wringing machine. The large wooded drum, around which the tracings and printing paper pass, is moved either by a connection with the shafting or by an electric motor mounted on the apparatus, the speed of the drum being regulated by a device shown on the top of the machine. A traveling apron of transparent material takes the place of the glass in the printing frame of the ordinary type, and as it is under tension at all times, it insures an even and close contact at all points. This apron is wound on a small drum at the top, and after passing along the large drum where the contact and exposure take place, it is wound up on the drum below; after the printing operation has been completed it is re-wound by hand back on the upper drum. In the rear of the machine are three arc lamps with reflectors, which concentrate the light on the tracings which, with the exposed prints, drop out into the box in front. The blue paper may be kept in a roll ready for use on the upper front part of the machine, or may be fed in small sheets with the tracings where the work being done is of ordinary size.

The machines are made in two widths, 30 and 42 inches; the apron supplied with them is 70 feet long, and prints of this size can be made as readily as smaller ones where it is desired. The ability to make prints of this size greatly enlarges the sphere of usefulness of the blueprint.

A feature of this machine quite as valuable as its capacity for making large prints is the fact that it can be readily turned into a sun-printing machine. At such times as the sun is available this represents an economy of some considerable moment, for it not only saves the cost of the current, but also makes the prints somewhat quicker, thereby increasing the capacity of the apparatus.

Electric Boat. See **ELECTRIC NAVIGATION.**

Electric Bridge, a term applied to an arrangement of electrical circuits used for measuring the resistance of an element of the circuit. The most generally known and used are the Wheatstone "bridge" or "balance," and that of the British Association.

Electric Burglar-alarm. See **ELECTRIC SIGNALING.**

Electric Call-box System. See **ELECTRIC SIGNALING.**

Electric Candle, a modification of the arc form of electric light, in which the carbon pencils are parallel and separated by a layer of plaster of Paris. Invented in 1877 by Jablochhoff, a Russian engineer. This invention is noteworthy as having revived an interest in electric illumination. See **ELECTRIC LIGHTING.**

Electric Chimes, in frictional electricity, a group of three bells hanging from a brass frame. The middle bell is suspended by a silk thread, but carries a chain connecting it with the earth; the other bells are suspended by chains. Between the bells two small metal balls are hung by silk threads. The apparatus being connected with the conductor, and the machine set in action, the outer bells become charged with electricity; the little balls are first attracted, then repelled toward the middle bell; coming in contact with it, their electricity is discharged.

Again they are attracted by the other bells and again repelled, and so on successively. Thus the balls oscillate backward and forward between the bells, and striking them with some force, a constant ringing is kept up.

Electric Clock, a dial with hands and going-train impelled by recurrent impulses from an electro-magnet. The first known clock of this kind was invented by Wheatstone, and exhibited by him in 1840. Appold, Bain, Shepherd, and others have contrived clocks on the same principle.

Electric Column. See **DRY PILE.**

Electric Condenser, an apparatus for accumulating or condensing electricity. A simple form of it consists of a glass disk with a disk of tinfoil of smaller diameter pasted upon each side. To use it, the glass disk is held by the rim and the tinfoil is presented to the prime conductor, while the other tinfoil is touched with the finger of the other hand. The machine being set in action, the positive electricity bespreads itself over the foil; this acts by induction on the other foil, repelling the positive fluid through the body of the experimenter, and attracting the negative to the side next the glass. Thus in a short time two layers of electricity, positive and negative, are deposited on opposite sides of the glass; they hold each other in bondage, and are unable to unite in consequence of the non-conductibility of the glass. If now the experimenter desires an individual to touch the foils with his two hands, a smart shock is experienced, resulting from the union of the two electricities through his arms.

Electric Conductors. See **ELECTRICITY.**

Electric Cooking Apparatus, an American invention patented in 1903; an adjustable or flexible electric cooking device. It is based upon the use of heating coils or spirals enclosed within the cooking chamber, associated with portable heater trays in which the coils are grouped between plates. For utilizing these electric trays or heaters the inventor provides an oven or stove consisting of a casing into which the trays are inserted, so as to serve as shelves on which to place the articles to be cooked. The sides of the oven are provided with ledges or cleats for upholding the tray and so that any tray can be placed on any pair of cleats, and thereby set in the oven at any desired height. Removable grids or gratings are provided as shelves between the electric trays or upon ledges not occupied by the latter. The top of the stove is provided with stove holes, as usual, under each of which is provided a special electric tray or heater. For introducing the electric heaters in circuit they are provided with circuit terminals connected to the coils, adapted for connection with exterior conductors with the respective circuit leads; one or both of the connections consisting of a metallic socket in the heater connected with the coils and adapted to receive a metal pin or plug connected by a wire or cable with the stationary circuit lead.

Electric Currents. See **ELECTRIC ALTERNATING CURRENT; ELECTRIC DIRECT CURRENT; ELECTRICITY.**

Electric Density, or Electric Thickness, the quantity of electricity found on a given surface.

ELECTRIC DIRECT CURRENT

Electric Direct Current, as distinguished from the alternating current, is so-called because of the fact that it travels in one direction along a conductor. If this conductor joins the terminals of a source of energy as a dynamo (q.v.), the current is said to flow from the positive pole of the machine along the conductor to the negative pole.

Probably the first man to detect current electricity was Galvani about the year 1786. To Volta (q.v.), however, is certainly due the credit of first developing a practical electro-chemical cell. In the year 1800 Volta exhibited a cell known as the "Voltaic Pile," consisting of a series of disks, copper and zinc, alternately separated from each other by a cloth saturated with brine; on joining wires to the end disks, quite a perceptible shock may be felt by touching with the tongue or moistened finger, the two terminals simultaneously. This simple cell was the starting point of all the electro-chemical batteries of the present day. With the discovery of Volta of the laws of difference of potential between different metals when placed in contact or joined by a fluid electrolyte, began the development of very many varieties of cells, all on the same principle; yet even now, the two metals he chose, zinc and copper, constitute the elements of the Daniel cell very frequently used for telegraphic purposes. The changes which would readily suggest themselves in Volta's first cell would be, increasing the amount of corroding liquid and placing the elements, zinc and copper, in a vessel which would properly contain the fluid.

The theory as given by Gore of the electro-chemical cell is as follows:

"The essential cause is the stored-up and ceaseless molecular energy of the corroded metal and of the corroding element of liquid with which it unites, while contact is only a static condition; and chemical action is the process or mode by which the molecular motion of these substances is more or less transformed into heat and current."

The electromotive-force of chemical generators is small, rarely exceeding two volts per cell. This necessitated a large number of cells connected in series; that is, the positive terminal of one connected with the negative terminal of the adjoining cell, the electro-motive force thus produced being the product of the electromotive-force of one cell by the number of cells. By connecting the similar terminals, that is to say, the two positive and the two negatives, an increased quantity of current can be obtained at the potential of one cell. The first method is called joining battery cells for intensity and the second for quantity. It is known that the energy generated in a chemical cell is produced by the consumption of zinc. The cost of this energy must necessarily be high as both zinc and the chemicals are expensive, so that the use of current electricity was quite limited until the introduction of the dynamo electric machine which might be called the mechanical method of transforming energy from some source such as a steam engine into current electricity as contrasted with the chemical method.

In the year 1831 Faraday discovered and announced the principle of electro-magnetic induction. This opened up the field of what might be

called the commercial generation of current electricity. The principle discovered by Faraday, which forms the basis of all dynamo electric machines, is that if a wire is moved in a magnetic field, so as to cut the lines of force, a current will be generated in the wire, and it is upon this principle that all dynamo electric machines depend for their action. The converse of this law, he also announced, that when an electric current is applied to the dynamo by some external source such as the battery or another dynamo, the machine will furnish mechanical power so that a dynamo electric machine may be considered either as a generator or as a motor.

All dynamos consist of two essential parts, one, the field magnet, which is usually stationary, and the other, the armature on which the copper conductors are mounted and which revolves on a shaft between the poles of the field magnet. This armature is so arranged as to cut the lines of force flowing between the magnetic poles. The lines of force are imaginary lines flowing from the north pole to the south pole of any magnet. They can easily be traced by placing a piece of paper above the magnet and sprinkling on this paper iron filings. If the paper is covered with mucilage the filings will maintain a permanent position so that they may be studied at the leisure of the student.

The field magnets may be made of steel, magnetized, or preferably they may be electro-magnets made of soft iron over which a coil of wire is wound carrying a current of electricity which induces magnetic lines in the iron. It is to be noted that if the ends of the magnet (q.v.) are bent in the form of a horse-shoe, the lines will be intensified by the reduction of the air space between the poles, and as the amount of current induced in the wire depends on the number of lines of force cut, the greater the strength of the field magnets, the greater will be the current induced.

Considering first the ideal simple dynamo: This would consist of a single loop mounted on centres rotating between the poles of a magnet, each end of the loop being connected to a collector which in direct current machines is called a commutator, and is mounted on the shaft outside of the poles, and insulated therefrom. If the loop is placed in a vertical position and moved through 180° , each side will pass through the whole number of lines of force flowing between the poles which will induce a current in one direction in the loop. If the rotation is maintained in the same direction during the next 180° it will cut the lines of force in the opposite direction, that is, the lines of force will be passing through the loop in the opposite direction to that in the first case. This will induce a current which will be in the opposite direction from the current induced through the first half of the revolution; so that the current will be pulsating, first in one direction and then in the other during each revolution. If the collector or commutator be cut into two halves parallel with the shaft and the ends of the loop be connected one to each half and if a pair of brushes be supplied to collect the current, one above and one below the commutator; when the loop is vertical, the brushes will be changing contact from one end of the loop to the other and as no current is

ELECTRIC DIRECT CURRENT

then being generated, the change is made without sparking and current flowing in the same direction continuously can be obtained from the brush terminals. During the moment of changing from the one contact to the other, the circuit is momentarily opened or interrupted. This would cause sparking at the brush or collector, were it not that the brushes are placed at a point at which the current is practically zero. This is found in practice to be slightly in advance of the theoretical neutral point on account of lines of force being dragged in the direction of rotation by the conductors.

To advance from the ideal simple dynamo:—the next step is to reduce the air gap between the poles of the field magnet and concentrate the lines of force in the effective space. This is accomplished by placing an iron core on the armature which in the first place reduces the magnetic resistance of the air gap and thus increases the number of lines of force through the armature conductors, and also serves as a support for them. Other machines were built with shuttle wound armatures, the armature consisting of an iron shuttle cut out with grooves longitudinally to take the conductors. These were usually wound with a number of turns of copper wire, the ends being brought out to a two-part collector or commutator. (See **ELECTRIC ALTERNATING CURRENT**.) The next step was to add to the number of coils on the armature so that during each portion of a revolution, some part of the armature conductors would be doing maximum work. Should an additional coil be added to the ideal generator, at right angles to the first coil, the capacity of the machine will be doubled. This complicates, to some extent, the collector rings and may necessitate the opening of the circuit when current is flowing so as to cause sparking and burning of the brush. A machine built on these lines would, therefore, be better adapted for generating small currents as the sparking at the brushes would be otherwise very destructive to the commutator. Machines of this type are known as open coil.

The next important step was made by Gramme and Pacinotti, which was to close the coils with themselves so as to form a continuous circuit in the armature and connect from each coil at its junction with the next one to the collector sections, the number of sections being the same as the number of coils. In the four-coil armature, the current generated can either pass to the collecting brush directly or when it moves out of position so that the contact is broken and made with the next section, the current can flow through the armature coils to the same brush if necessary, and when that coil passes from one polar position to another and is giving current of opposite polarity this current can flow directly to the other brush, and so continuous current is generated. There is also no point at which the circuit is open. There may be a slight sparking as the section moves from the brushes, but violent sparking is reduced as there is always another path for the current to flow to either brush.

The drum armature is distinct from the ring armature in that the wires are wound on the outside of the core and do not pass through it. This type is frequently called the "Siemens'" armature on account of the number of suc-

cessful machines built by Siemens. Of the whole number of lines of force passing between the poles and through the core, there are very few lines passing in the inside, they being diverted by an iron core so that they pass through the wires on the outside of the core; the conductors inside of the core are thus of little use, their only function being to complete the circuit and carry current between the successive turns on the outside of the core; so that by winding the wires on the outside surface only, the amount of idle wire is reduced, the only material that is not active being the cross-connecting pieces at the ends.

The Gramme ring was used very largely on early machines for the reason that it afforded means for easier mechanical construction, and machines of this type were generally successful, on account of their simplicity. Pacinotti designed a core having teeth similar to a gear wheel. In this way the air gap between the armature and pole pieces could be reduced somewhat, resulting in an increased number of lines of force. It also afforded an additional support to the coils and added to the mechanical strength of the machine.

To be considered next are the field magnets: There are a number of constructions which may be employed. (1) The so-called permanent steel magnet which consists of a bar or bars of steel bent to the shape desired, tempered and magnetized. The method of magnetizing these magnets consisted of placing them in contact with other magnets or with an electro-magnet. The present method would be to insert the steel bar into a helix carrying a heavy current and in a short time the bar would be magnetized. The dynamos built with permanent steel magnets of this type are what is known as magneto dynamos. The chief objection to this form of magnets is that a steel magnet cannot be made as powerful as an iron magnet which is energized or as it is commonly called, excited from a source of electricity. In the first generators permanent magnets were used, but a great step in advance in dynamo design was to arrange the magnet poles so as to be self-excited. A portion of the current generated in the armature is sent around the coils wound around the cores of these field magnets so as to excite them. At first, however, magnets were substituted consisting of soft iron upon which was wound a coil of copper wire, the current for energizing these pole pieces being first supplied from a small magneto generator or a voltaic battery. Sometimes the machine will not generate on starting up sufficient current to excite the magnets and it is necessary to excite them from some external source so as to give the initial strength to the magnets and allow them to build up from the current generated in the armature. It is usually found that there is sufficient residual magnetism left in the iron of the field magnets, after the machine has once been in operation, to start the current in the machine and properly build up the fields.

In regard to field windings, two distinct types are used: (1) the series winding, in which all the current generated in the armature passes around the field poles and thence out to the line or circuit; and (2) the shunt winding in which a portion only of the current is used in the field, the connection being made across the main ter-

ELECTRIC DIRECT CURRENT

minals of the generator. In the first case the wire on the field windings is necessarily large so as to carry all the current for which the machine is designed and in the second case it is a small wire of many turns, the product of amperes and turns being about the same in either case. In another design, both a shunt and a series winding of a few turns is employed, constituting a compound winding.

It will be seen that in the first case, that of the series winding, the field strength will depend upon the resistance of the total circuit including the resistance of the armature, the field winding, and the external circuit. In a machine of this type the voltage or pressure generated will vary in proportion to the demands. This is the standard winding for the series arc machines used for city lighting such as the Brush and Wood types. In the case of the shunt-wound machine the current flowing in the field coil depends upon the pressure between the generator terminals, so that with an increased out-put and consequent loss in the armature the voltage will fall off slightly, thus reducing the field strength. This necessitates some means of varying the field current so as to maintain a uniform pressure at the generator terminals. This is usually accomplished by means of an external resistance in the field circuit composed of German silver or iron wire which can be varied by means of a switch-head so arranged as to cut out certain portion of this resistance step-by-step and so increase the current through the fields, thus preserving a uniform voltage.

In a combination of series and shunt windings commonly called the compound type, as the output of the generator is increased, there is a greater flow of current through the series windings and consequent increase of magnetic strength of fields so that it is possible to compensate for the loss due to the resistance of the armature windings and maintain a uniform pressure at the generator terminals. The output of the dynamo depends upon the strength of the field magnets, the magnetic permeability of the material and the rate at which the lines of force are cut by the armature conductors so that the higher the speed, the greater the output of the dynamo. In the early machines very high speeds were common, armatures of small diameters being employed. These were objectionable for mechanical reasons so that the design was changed in order to increase the number of pole pieces. Instead of the field being composed of two poles, it was arranged so that a greater number of poles could be used, this type of machine being known as the multipolar dynamo. As each conductor would pass between a number of poles during each revolution the speed could be proportionally reduced.

The dynamo, as previously stated, is a machine for converting energy in the form of mechanical power into electrical power, or vice versa, so that a motor is a machine for converting energy in the form of electricity into mechanical power. The early types of motors were based on the principle that a magnet would attract the opposite pole of another magnet, and if one set of magnets is arranged on a wheel, and the other stationary, the movable magnet will be drawn around. To make this effective

it will be necessary to interrupt the forces at what might be called the dead centres so that the wheel would have continuous motion. This is accomplished by either introducing a screen, or, more satisfactorily, by the use of electro-magnets with a movable contact so that the magnets are energized intermittently, allowing the wheel to revolve in accordance with impulses received from the magnetic poles.

When we consider the dynamo as a motor, the current supplied to the terminals will take two paths, one through the armature and the other through the field coils. The field current energizes the pole pieces, and the current traveling in the armature is similar to another magnet inasmuch as a coil carrying the current will be attracted or repulsed by a magnet according to the directions of the current through the coil, so that the wire will be forced around by attraction and repulsion. By considering the effect of the commutator the motion is seen to be continuous. When the armature starts to revolve the conditions then existing will be similar to the armature in action as a dynamo resulting in an electro-motive force being generated in the armature wires, which will be in the opposite direction to the incoming current. This is what is called the counter electro-motive force of the motor, and will tend to reduce the amount of current which will flow through the armature conductors. It is, therefore, evident that when a motor is started there will be a rush of current through the armatures, as the resistance is very small, and as there is no counter electro-motive force while the machine is not in motion to check the flow. For this reason, in the direct current motor it is necessary to introduce an external resistance into the armature circuit to hold back the current which would flow until the machine reaches full speed. The resistance is then gradually reduced until full speed is obtained. The effect of this counter electro-motive force when the resistance is cut out entirely is to materially assist the self-regulating qualities of the machine. Any load applied to the motor would tend to slightly reduce the speed, which effect, by also reducing the counter electro-motive force and allowing more current to flow through the armature, tends to keep the speed from falling much below normal in the shunt motor. Motors can be built either with a plain shunt field winding or with a series and shunt winding, depending on their requirements. The direction of rotation depends on the direction of the current through the armature. To reverse the rotation, therefore, it is only necessary to reverse the current in the armature, leaving field connections as they are. If the current is changed in both field and armature, the result would naturally be that the machine will continue to revolve in the same direction as before.

To reduce the speed of the direct current motor it is only necessary to add resistance to the armature circuit so as to limit the current flowing therein, and by so doing almost any desired speed may be obtained, from 1 per cent up to full rate of speed. There are a number of other methods by which variable speeds can be obtained, one of them being by varying the field strength. Any motor, however, operating at a lower field or armature current than normal conditions would require is naturally operating at reduced power. On account of the valuable

ELECTRIC DISCHARGE — ELECTRIC FIELD

features in relation to speed control, the reversability, and the automatic speed control inherent in shunt machine, together with a large torque of the series machine, the direct current motor fulfils more nearly than any other the practical requirements in machine-shops, textile mills, and general manufacturing establishments.

For electric railway work all over the world the direct current is employed. (See TRACTION, ELECTRIC.) The compound wound generator and series motor being standard practice. Often this type of generator is over-compounded so as to more than overcome the drop through the armature resistance and allow higher voltage at full load than at no load, so as to overcome, in a way, the drop of potential on the feeders and preserve the uniform voltage over the system. In lighting and power work the shunt and compound dynamos are both used. (See ELECTRIC LIGHTING). And in the business centres of our large cities where the direct current is generally used, the rotary converter fed from a high tension alternating central station is very often employed, together with storage battery. One of the chief reasons why the direct current is used so generally in preference to the alternating, outside of the fact that more satisfactory motor may be obtained therefrom, is the total absence of all inductive effects so troublesome in large secondary alternating systems, where the pressures are low and the currents very large. A much more uniform pressure can be kept on the supply mains of a direct current system than an alternating one, especially if many large motors are connected, and this fact, together with the use of the storage battery, which can only be used on direct current systems (for other information on storage batteries see article on STORAGE BATTERIES), enables the large lighting companies to use a very efficient type of incandescent lamp, which, being generally freely renewed by the company, by its longer life aids materially in keeping up the value of the business.

The shunt and series motor each has its own field of usefulness. When a very powerful starting torque and rapid acceleration are necessary the series motor is used, as in the case of street railway, electric locomotives, electric cranes; and on steamships where the direct current alone is used, as on the Kentucky and Kearsarge, of the United States navy, not only is electricity used for lighting, but also for operating ammunition hoists, hoisting anchors, operating boat cranes, and even the steering gear of the ship itself.

In machine-shops and manufacturing establishments where a more or less constant speed may be required, and in elevator work, the compound and the shunt motor are commonly employed. The shunt motor is very well adapted for operating at any speed desired, and for machine tools it is at present without a peer for an efficient and easily regulated source of power. Unlike the series motor, where the speed varies with the load, the shunt motor is practically a constant speed machine. When thrown on the lines it rapidly comes up to normal speed, and then from no load to full load will not greatly deviate therefrom unless purposely thrown to a slower point of the controller. As a series motor would run away if left in a circuit with a load suddenly removed, the shunt motor, or sometimes the compound, which is used in order to preserve an absolutely uniform speed from no load to full load, and is necessary in a few places

where absolutely constant speed is required, is the standard motor for driving textile machinery in large mills, factories, and other establishments.

Direct current is more suitable for general requirements than alternating current. It is essential to use direct current to charge storage batteries. Storage batteries fulfil an important function in direct current distributing systems, as by this means a reservoir is established which is useful in taking care of sudden demands caused by the consumer, or it may take the place of defective generators or apparatus.

WM. C. L. EGLIN,

Chief Engineer Edison Company of Philadelphia.

Electric Discharge, the escape of electricity, whether slowly and silently, or more quickly and violently, from any receptacle or generator.

Electric Door-bells. See ELECTRIC SIGNALING.

Electric Drill, a drill for metals or rock worked by an electromagnetic motor. For metals a rotary motion, for rocks a reciprocating or percussory action, is imparted.

Electric Eel (*Electrophorus electricus*), a great eel inhabiting the marshy waters of the llanos in South America. It belongs to the family *Gymnotidae* and order *Plectospondyli* (qq.v.), and with a few allied species is distinguished from all other eels by the partial coalescence and modification of the anterior vertebrae. It is remarkable chiefly for the great size of its electric organs, which consist of two pairs of longitudinal bodies between the skin and the muscles of the caudal region, divided into about 240 cells and supplied by more than 200 nerves. The eel can discharge sufficient electricity to kill an animal of considerable size, and is said to possess power, when in full vigor, to knock down a man and benumb the limb affected, in the most painful manner, for several hours after communicating the shock. By frequent use of this faculty it becomes impaired, and a considerable interval of rest is required to recruit its electrical properties. According to Humboldt the natives of South America make use of horses in taking the electric eel. The animals are driven in a body into a stream or pond where the fishes abound, and the latter, having exhausted their stores of electricity by repeated attacks upon them, are then easily taken. The horses are sometimes so severely stunned by the shocks that they fall and are drowned. Specimens of the *Electrophorus electricus* are reported to attain the length of 6 or 7 feet, but ordinarily they are about 3½ or 4 feet long. The flesh is eatable and is said to resemble that of the common eel in appearance and flavor. See ELECTRIC FISHES.

Electric Egg, an ellipsoidal glass vessel, with metallic caps at each end, which may be filled with a feeble violet light by means of an electric machine acting on it after a vacuum has been made inside the glass.

Electric Elevators. See ELEVATORS.

Electric Escapement, a device actuated by electric impulse which intermittently arrests the motion of the scape-wheel and restrains the train to a pulsative motion—acting, in fact, in the place of a pendulum.

Electric Field, any space wherein electric force exists. See ELECTRICITY.

ELECTRIC FIRE-ALARM — ELECTRIC FURNACES

Electric Fire-alarm. See *ELECTRIC SIGNALING*.

Electric Fishes, several quite unrelated fishes which possess the extraordinary property of communicating an electric shock to animals with which they come in contact. The organs which are the source of this power have been much studied by both anatomists and physiologists. They are in all cases — with the possible exception of *Malapterurus* — formed by the modification of muscular tissue, and consist of a mass of numerous closely packed prisms, each divided into a series of compartments filled with a gelatinous substance. One surface of the fibrous disks thus formed receives a rich nerve supply and is electrically negative, the opposite surface being positive. The entire organ may therefore be likened to a group of voltaic piles. Among the *Elasmobranchii* (q.v.), many of the skates possess rudimentary electric organs, which reach a high degree of development in the torpedo (*Torpedo*, q.v.) and an allied genus (*Hypnos*). In these two genera the organs occupy a large area on each side of the head and the prisms are arranged vertically and are supplied by large nerves, four pairs of which arise from a special electrical lobe of the hinder part of the brain, while a fifth is a branch of the trigeminal. In the electrical catfish (*Malapterurus electricus*) of the Nile, and some allied species, the entire body is enveloped by an electric layer beneath the skin and the muscles. In the electric eel (q.v.) and all other electrical fishes the organ is placed by the side of the tail and the prisms are disposed longitudinally. Not alone in structure but in the phenomena of rest and activity these organs bear a striking resemblance to muscles, which also normally exhibit weak electrical currents.

Electric Fluids. In order to explain electrical phenomena a theory was propounded by Dufay and Symmer, and now very generally adopted among physicists. The "theory of electric fluids," as it is called, is as follows: That every body contains an indefinite quantity of an imponderable subtle fluid, that this fluid is composed of two fluids which are self-repulsive but mutually attractive. When a body is in its natural state, the two fluids are in combination, and neutralize each other. The act of electrification consists in the forcible separation of the two fluids, whereby one is diffused over the body rubbed and the other over the rubber, one kind of electricity never appearing without an equal quantity of the other. This theory, however, must be regarded as a mere provisional conception, and not a proved scientific truth.

Electric Furnaces. Electric furnaces are devices for localizing the heat of an electric circuit and utilizing it. In the usual technical use of the term a comparatively high temperature is developed for the purpose of effecting a chemical reaction or producing a change of state in the substance to be treated, such, for instance, as the reduction of an ore, the formation or disruption of a compound, or the fusion or volatilization of a metal or compound. Electric furnaces comprise means for developing the necessary heat at the point or points desired, and for subjecting the material to be treated, technically known as the "charge," to the influence of this heat. The several types or classes

of electric furnace will be briefly described according to the principles employed. The heat development in any given portion of a circuit is proportionate to the resistance offered to the passage of the current; hence those portions of the circuit external to the furnace proper are always composed of metals which conduct the current well, and generally of copper or aluminum, whereas the resistance of those portions of the circuit in which the heat is to be localized is relatively high. These latter portions of the circuit may consist of gases, in which case an arc is formed and the localization of the heat is extreme; of substances of high melting and boiling points, in a state of fusion, when an electrolytic effect, to be hereinafter more fully referred to, usually supervenes; or of solids, such as platinum and other difficultly fusible metals, carbon, graphite and carbonaceous mixtures, or such bodies as the oxides of the alkaline earths which become conductive when heated. These three classes of furnace, wherein the heat is localized in a gas, a liquid, and a solid, respectively, may be conveniently designated by the terms arc furnace, electrolytic furnace, and incandescent furnace, although as will appear it is not always easy to apply one or another of these names to the actual constructions. Although electrically developed heat is relatively costly, the fact that it can be locally applied, within the interior of the charge if so desired, is an important advantage, and the utilization of the heat is often so complete that its use represents a real economy. The heat lost is that which is carried from the furnace by the escaping products of the reaction, and that which is conveyed by radiation, convection, or conduction, from the walls, the electrodes, and other exposed portions of the structure. Inasmuch as the exposed surfaces of a furnace are roughly proportionate to the square of its dimensions, whereas its capacity varies as the cube, it is evident that other things equal, the larger the furnace the less will be the percentage of total heat which is lost and the greater will be the efficiency. This indicates the employment of large units. It is always possible to reduce the expenditure of electrical energy by making use of heat otherwise generated, such heat being employed for raising the temperature of the charge previous to its introduction into the electrically heated zone, or for heating the exposed surfaces of the furnace structure in order to check radiation therefrom. Furnaces in which chemical reactions are conducted, as, for instance, those in which calcium carbide is produced, often yield gaseous products which are not only themselves very highly heated, but are capable, by combustion, of further heat development. It has frequently been proposed to utilize this heat by conducting such gases through or around the incoming charge or by burning them in flues surrounding the furnace, but the greater complexity of the structure and the difficulty of purifying the large volume of dust-laden gas constitute practical difficulties of a serious nature.

The Arc Furnace.—When an electric arc is formed in air between carbon terminals there is observed to be a definite limit to the length of arc which can be maintained with a given current strength; furthermore this limit which at first increases almost in proportion to the current strength, increases very slowly as the

ELECTRIC FURNACES

current density reaches higher values. The maximum length of the arc is therefore limited. The temperature of the carbon terminals may attain $3,500^{\circ}\text{C}$., at about which point, under atmospheric pressures, carbon volatilizes. The temperature of the incandescent gases of the arc is perhaps a thousand degrees higher. It follows that the arc furnace, in its simplest form, is adapted particularly for subjecting small charges to extremely high temperatures, and its value for experimental work is apparent. For use upon a commercial scale it is generally necessary to so distribute the heat from the arc that a comparatively large body of the charge may be acted upon in a given time. This result may be accomplished by establishing a plurality of arcs in adjacent portions of the charge, by exposing the charge to the heat radiated from one or several arcs not in contact with it, by causing the arc to move relatively to the charge, or by moving the charge through or past the arc. The temperature of that portion of a charge which is in immediate contact with an arc may be practically that of the arc itself and is uncontrolled; the operations for which this method of procedure is suitable and economical are relatively few. The high temperatures which the electric furnace is capable of producing have opened a new field to chemistry, but in order to insure the formation, in theoretical quantity and in a state of purity, of many compounds, a careful regulation of the temperature is essential; for the highest attainable temperatures are capable not only of giving rise to new combinations but also of breaking them down, resolving them into simpler bodies or even into their elements. A single instance of the importance of heat regulation may be offered: If a mixture of sand and coke be cautiously heated in an electric resistance furnace a partial reduction of the sand occurs, and a product containing silicon, oxygen and carbon and known as "siloxicon" is formed; at a somewhat higher temperature the reduction is complete and there results an amorphous body having the essential composition of carbid of silicon and technically called "white stuff"; at somewhat higher temperature ranges this amorphous body passes into the crystalline carbid of silicon "carborundum," a compound approximating in hardness the diamond itself; and at still higher temperatures, approximating those of the arc, this carborundum is broken down, its silicon escapes as a vapor, and its carbon remains in the form of graphite. The effect of high temperatures upon reactions is two-fold: in the first place the velocity of the reaction is increased, so that chemical changes which at lower temperatures occur slowly or not at all take place rapidly or even with explosive violence; in the second place new conditions of equilibrium are established, and the chemical elements, entering into that combination which, under the circumstances, is the most stable, sometimes give rise to compounds not before known. To produce a given result, however, it is usually necessary to work within definite temperature limits, and since the heat of the arc cannot well be controlled, it is necessary to govern the temperature of the charge by limiting the duration of its exposure to this heat. As above pointed out, this may be accomplished by moving the arc through or near the charge or by moving the charge through or past the arc, the duration

of contact being so adjusted to the quantity of charge and to its specific heat as to bring it to the desired temperature. As a rule, however, the arc as a source of heat is both wasteful and inefficient.

The Electrolytic Furnace.—When a direct current of sufficient volume is caused to pass through a molten salt not only will the salt be maintained in fusion by the heat developed by its own resistance, but it will be "electrolyzed," that is to say, it will be decomposed in such manner that one of its component parts, which may be a metal, will tend to accumulate at one electrode, while another component, which was before in combination with the metal, will appear at the other electrode. That electrode at which the current is assumed to enter the molten bath, and at which the negative or non-metallic portion of the compound appears, is called the "anode," while the other electrode, which receives the positive or metallic element and at which the current is considered to leave the bath, is designated the "cathode." Thus if common salt, sodium chlorid, be fused and traversed by a direct current, the negative element chlorin will appear at the anode and the metal sodium at the cathode. If the substance of either electrode be such that the element liberated in contact with it can combine with or dissolve in it, the corresponding compound or solution will be formed: If, for instance, the fused sodium chlorid be electrolyzed with an anode of carbon and a cathode of molten lead, chlorin will be evolved at the anode and escape from the bath, while sodium, dissolving in the lead, will yield an alloy from which the metal sodium, or its hydroxid caustic soda, may be obtained. In electrolytic furnaces also it is essential to carefully regulate the temperature, not only because an unnecessarily high temperature means a waste of energy, but because of losses arising through volatilization of the bath and the recombination of the separated products of the electrolysis. So important is this last factor that in certain cases, as, for instance, in the separation of metallic sodium from molten caustic soda, it is absolutely essential to the success of the process that the temperature be maintained within limits of a few degrees only.

The Incandescent Furnace.—This term is commonly applied to those furnaces wherein the heat is developed by the passage of the current through a body which initially at least is solid. Such body may comprise a rod or core of carbon or carbonaceous mixture; a granular bed or core consisting of fragments of coke, retort carbon or graphite; the charge itself, often admixed with a quantity of carbon sufficient for its reduction; the furnace product when this is conductive and possesses a volatilizing point sufficiently high to permit the necessary temperature to be attained; or a pyroelectrolyte, that is to say, an oxid or mixture of oxids which is normally non-conductive or substantially so, but which while remaining unfused becomes capable at temperatures considerably above the normal of carrying the current. Each of these resistance materials possesses its advantages for particular lines of work, but all have in common the advantage of permitting accurate and ready adjustment of the temperature by varying the amount of current passing. These incandescent furnaces have, therefore, the widest applicability, and in case the resistance

ELECTRIC FUSE—ELECTRICITY

material used is carbon the maximum temperature attainable is probably not inferior to that of the terminals of the electric arc. The above defined types are not always sharply distinct, but under certain conditions the operation proceeds under two or perhaps all three of the methods. Thus if the resistance consists of fragments of carbon, the current may traverse the interspaces in the form of minute arcs; and if this fragmentary carbon be commingled with a suitable ore or compound there may be present also an electrolytic effect; the primary fusion of an electrolyte is often accomplished by means of a resistance rod connecting the electrodes, or this fusion may be accomplished by the arc. Furthermore a given furnace structure is often capable of either mode of operation according to the character of the charge and the adjustment of the electrodes with reference thereto. The most important as well as the most characteristic applications of the electric furnace have relation to certain elements and compounds which cannot be produced directly, if at all, by other means. See ELECTRO-CHEMISTRY; ELECTRO-CHEMICAL INDUSTRIES.

CLINTON PAUL TOWNSEND,

Member of American Electro-Chemical Society.

Electric Fuse. (1) A device used in blasting to explode the charge. The fulminate or the charge itself is lighted by means of an electric spark or a resistance section of fine platinum wire, which is heated to redness by the passage of an electric current induced by a voltaic or magneto-electric battery. (2) A safety device used to protect electric circuits against too great a volume of current. The melting of the fuse will stop the current by breaking the circuit.

Electric Gas-lighting, lighting gas by an electric spark. Illuminating gas is principally composed of two elements, carbon and hydrogen, both of which also have a strong affinity for oxygen, but, like phosphorus and sulphur, they will only unite with it when their kindling temperature is reached. In lighting gas with a match all we do is to heat the gas up to this point. But we may light it just as well by any other means that will give the required heat. A piece of red-hot wire will do it. An electric spark does it. There is very little heat in the spark itself, but very little is needed. It is degree of heat required, not quantity. If one tiny particle of hydrogen can be made hot enough to unite with oxygen, it will heat up its neighboring particles and spread the flame in an instant.

Electric Generation. See GENERATION.

Electric Generator. See DYNAMO; ELECTRIC MACHINE.

Electric Governor, a governor in which a part of a fly-wheel, say a segment of the rim, is made to move radially outward when the wheel revolves at a rate above a preappointed speed, and thereby comes in contact with a metallic tongue, completing an electric connection, which is utilized to move a butterfly valve or other device which concerns the transmission of power. Governor-balls flying out to a certain distance may make or break an electric connection to produce the same result, or sound an alarm.

Electric Hammer. See HAMMER.

Electric Harpoon, an application of the electric current to the explosion of a bursting charge in a harpoon or bomb-lance. A copper wire is carried through the line, and when a circuit is established by the harpooner, a resistance section in the fuse of the bomb-lance ignites the charge.

Electric Heater, a form of electric heater based upon the principle of electrical resistance. Some resistant body, such as carbon or platinum, is placed in the circuit, and retains heat upon the passage of the current in proportion to its qualities of resistance.

Electric Helix, a coil of copper wire in the form of a screw. The wire is generally coiled around a bar of soft iron, and when an electric current is sent through it, this confers polarity upon the iron, the wire and iron together constituting an electro-magnet. The helix will also manifest magnetic properties without any iron bar.

Electrician, ē-lek-trish'an, one who makes a study of electricity or who makes or manufactures electrical appliances.

Electric Induction. See ELECTRICITY; INDUCTION.

Electricity is a form of energy (q.v.) like mechanical energy or energy of motion, heat, radiating energy as light, chemical energy, etc. Electric energy is the form of energy most recently introduced into everyday life and is, therefore, not yet quite familiar, so that we still ask, "What is electricity?" while ages ago mankind ceased to ask, "What is gravity?" or "What is light?" although the manifestations of electric energy are no more wonderful and inexplicable than those of gravity, that is the cause why a stone falls to the ground and water flows down hill. In nature electric energy manifests itself during atmospheric disturbances as lightning (q.v.), but the energy of lightning is too erratic for use. For the production of electric energy on a larger scale recourse must be had to the stores of energy afforded by nature. In large amounts energy is found in nature, first, as mechanical energy in the waterfalls and to a lesser extent the wind, and second, as chemical energy in coal, wood, oil, natural gas, etc.

Generation.—In the transformation of the mechanical energy of waterfalls into electric energy, the water-power is first converted into rotary motion by the turbine or water-wheel, the latter then converted into electric energy by the electric generator or dynamo. Chemical energy can be converted directly into electric energy only to a limited extent, as chemical energy of metals. This is done in the electric battery. (See BATTERY.) But due to the high cost of the chemical energy of metals, the production of electric energy by means of the battery is commercially feasible only where small quantities are required and the cost of the energy therefore secondary to the convenience of generation, as for signaling purposes, bells, annunciators, etc. The chemical energy of coal and other combustibles cannot be directly converted into electric energy, but is converted into heat energy by combustion, the heat energy transferred from the gases of combustion to the water in the steam boiler, converted into mechanical energy in the steam engine and the mechanical converted into electric energy in the

ELECTRICITY

electric generator. In the gas engine the heat energy of combustion is directly converted into mechanical energy. In any transformation of energy from one form to another a certain loss occurs by conversion into heat. This loss is moderate in the transformation of water-power into mechanical energy, very small in the transformation of mechanical into electric energy, but enormous in the transformation of heat into any other form of energy. Our modern theories consider all forms of energy as different modes of motion; of the masses in mechanical energy or of the molecules and atoms of matter with electric, chemical, etc., energy. Heat is the simplest form of energy, irregular motion of the molecules or motion without definite speed and direction. It is, therefore, intelligible that in any conversion of energy, that is of a regular motion into another regular motion, some of the energy is lost by losing its regularity of motion, that is converted into heat, the more the greater the difference between the two forms of motion, and that when converting irregular into regular motion, that is heat into other forms of energy, this loss is specially great. The cost of electric-power derived from water-power does not differ much from that derived from coal by the steam engine, the cost of coal in the latter case offsetting the interest on the greater investment required in developing the water-power and transmitting the electric-power to the place of consumption. Hence where coal is cheap the steam-power may be more economical where water-power is found which can cheaply be developed, or where coal is expensive water-power is more economical.

Use.—Electric energy is hardly ever used as such but only after transformation in other forms of energy, mainly mechanical energy, heat, chemical energy, and light. Since electric energy is generated from other forms of energy, it follows that it is used essentially as intermediary form of energy. For this it is better suited than any other form of energy, due to the high efficiency and simplicity of generation and re-conversion, and especially the almost unlimited flexibility which permits transmission over long distance, distribution with the simplest means, and unlimited subdivision and ease of control.

Mechanical Power.—The electric motor is a secondary and not a primary source of power, that is, it does not convert the stores of energy found in nature into mechanical energy as the steam engine, but mechanical power has to be extended somewhere to produce the electric power which is re-converted into mechanical power in the electric motor. The advantage of the electric motor is that the mechanical power can be utilized at a distance from the source of power; the factories and mills may be located far distant from the water power and the railroad train or street car receive the power from the distant station. The power generated at one place can be distributed efficiently to a large number of places, or all motors of the city may receive their power from one central generating station. Instead of an extended and inefficient system of belting, individual motors may drive the machines of the factory or mill. All the cars or trains of a railway system may receive their power from one generating system, perhaps a water-power as Niagara. The electric motor is under more perfect control than

almost any other motor, and when not used consumes no power and requires no special care in starting and operation. Mechanical power in small quantities can be produced almost as efficiently as in large units and a great subdivision of power becomes thereby feasible. In the field of mechanical power generated by electricity also belong telegraphy and telephony, or the transmission of signals and speech over long distances.

Light.—For lighting, electric energy is first converted into heat and the light given by the incandescence of solid substances, exclusively carbon, the carbon filament of the incandescent lamp, or the glowing tip or crater of the arc lamp carbons. (See ELECTRIC LIGHTING.) Here again, especially with incandescent lamps, the main advantage lies in the absolute steadiness, control, and flexibility of the light, the simplicity of turning it on or off, and its relatively high efficiency, which gives a light with less heat than the gas flame or kerosene lamp. While due to the use of heat as intermediary form of energy only a very few per cent of the electric energy are converted into light, most being dissipated as heat, with the gas or kerosene flame the percentage of energy converted into light is still much less. Recently considerable work is being done and with great promise, of converting electric energy directly into light by electro-luminescence in luminous arcs, which promises an efficiency of light production very much greater than the incandescent or carbon arc lamp.

Heat.—The conversion of electric energy into heat means a degradation of energy from regular to irregular motion and in the heat production by electric energy only a very few per cent of the heat energy expended under the boilers of the steam engine driving the electric generator is recovered, so that electric heating is much more expensive than direct generation of heat by combustion and therefore commercially practicable only.

1. For the production of temperatures beyond those which can be reached by combustion. At very high temperatures chemical affinity and therefore combustion ceases and temperatures beyond this cannot be reached by combustion but are reached by conversion of electric energy into heat in the electric furnace. By this means chemical compounds have been produced for industrial purposes which were either entirely unknown or mere curiosities before, as the carbides, calcium carbide, carborundum, silicon metal, etc.

2. Electric energy is used for heating where the temperature has to be perfectly controlled.

3. Due to its convenience and cleanliness for domestic uses, to a limited extent, electric heating and cooking are coming into use.

Chemical Energy.—Electric energy is converted into chemical energy either directly in the electrolytic cell or indirectly with heat as intermediary in the electric furnace as discussed above. Electrolysis (q.v.), that is the chemical action of electric energy, is used exclusively for the production of aluminum metal, is used for copper refining, production of sodium, chlorates, soda, and bleaching powder, and many other compounds.

Storage.—Electric energy cannot be stored as such conveniently, but the ease and efficiency of conversion of electric energy into the chem-

ELECTRICITY

ical energy of metals and metallic oxides, and inversely, permits the storage of electric energy as chemical energy in the storage battery. (See ELECTRIC STORAGE BATTERY.) Charging the storage battery means converting in it electric energy into chemical energy, discharging, the re-conversion of the chemical energy into electric energy.

Measurements.—Since all forms of energy are convertible into each other they can be measured by the same measure. Heat being the simplest form of energy, the measure of heat is the universal measure of energy. It is the calorie, or the amount of heat required to raise one litre of water from 0° to 1° C. Chemical energy is exclusively measured in calories. All other forms of energy usually have some other measure convertible into calories. So, mechanical energy is measured in foot-pounds, or kilogram-meters, and the flow of mechanical energy, or mechanical power, in foot-pounds per second or horsepower, 1 horsepower = 550 foot-pounds per second = 75 kilogram-meters per second = .176 calorie seconds. The value of electric energy or electric power is measured either in the mechanical measure, horsepower, or electric measure, watts, 746 watts = 1 horsepower. Usually the kilowatt or 1,000 watts = 1.35 horsepower, is used. 1 kilowatt = .238 calorie second. Most forms of energy are resolved into the product of two components; a quantity and a pressure component, as the power of a waterfall is the product of the quantity of water flowing and its head or fall. So electric power is resolved into a quantity component called "current" and measured in amperes, and a pressure component called "electromotive-force" or "potential difference" or "voltage," and measured in volts, and the electric power then is a product of volts and amperes, 1 watt = 1 volt \times 1 ampere. Just as a small quantity of water under a high head may give the same power as a large quantity under low head, so a small current at high voltage may represent the same electric power as a large current under low voltage. The smaller the quantity and the higher the voltage the less the loss in transmitting the power. Therefore, for long distance transmissions high voltages are used, the higher the greater the distance, while relatively low voltages are employed for general use, due to the difficulty and danger of handling high voltages. The instrument measuring electric power is called the wattmeter, that measuring electric current or flow of quantity is the ammeter, that measuring electric pressure or voltage is the voltmeter.

Conductors and Insulators.—Some substances, as metals, carbon, salt solutions, etc., are conductors of electricity, others as air, glass, rubber, paper, oils, etc., are insulators. There is, however, no perfect conductor nor perfect insulator, but even the best conductors: silver, copper, aluminum, offer still some resistance to the flow of electric power and thereby cause a loss of energy which is proportional to the square of the current flowing and appears as heat in the conductor. For transmission of electric power conductors are therefore used to direct the flow of power, copper or aluminum, surrounded by insulators, as rubber, paper. It is not sufficient, however, merely to surround the conductor by insulating material, but the insulating material must have sufficient thick-

ness to withstand the electric pressure or voltage, otherwise it is disrupted, that is, the electric power penetrates it as spark discharge. The ability to withstand electric pressures is called the dielectric or disruptive strength and is of foremost importance in insulating electric circuits of high voltage. Very good insulators are not necessarily of very high dielectric strength, for instance air, which is perhaps the best insulator, has rather low disruptive strength, that is, is easily penetrated by an electric spark, while mica and rubber, although not as good insulators as air, have very much greater dielectric strength.

Physiological Effects.—Electric energy is perceived by the senses either indirectly by transformation into other forms of energy, as light and sound in the spark discharge or lightning, or directly if the electric current passes through the body. A large current of very short duration: an electric discharge causes a shock which when very powerful, as in lightning, may be fatal. A current flowing continuously through the body causes a specific sensation which with increasing voltage and therefore increasing current, becomes unbearable, the muscles contract and become uncontrollable, so that in case of accidental contact with electric circuits the victim is unable to let go, and ultimately at high voltages death may result. (See ELECTRICITY, CAUSE OF DEATH BY.) The amount of current flowing through the body depends upon the electric pressure or voltage and the resistance of the body. This resistance is mainly the skin or surface resistance, therefore depends upon the nature of the contact between body and electric circuit. When loosely touched with dry hands a 100 volt circuit may hardly give any sensation, while grasped with wet hands a 50 volt circuit may be unbearable. Only at very high voltages the nature of the contact becomes of less importance and the electric current penetrates as arc. Electric pressures of 500 to 600 volts are considered as still safe, since only in cases of exceptionally good contact with such voltages serious results may occur. Much higher voltages are usually fatal, but instances are on record of contact with 10,000 to 12,000 volts without fatal results, in cases where the duration of the contact has been very brief.

The causes of death by electricity are:

1. The direct effect of large power exerted upon the body, causing destruction by heat, etc., as in electrocution where several horsepowers are used.
2. Mechanical destruction of vital organs by very heavy discharges, as lightning.
3. Paralysis of the nervous system, stoppage of the heart and respiratory organs. In these cases resuscitation by artificial respiration, etc., when immediately resorted to, is very promising.

Therapeutically electricity is used as stimulant by its action on the nervous system and for carrying substances through the skin into the body electro-chemically. It is very useful in the hands of expert physicians but like any powerful agent in the hands of a layman, is harmful and dangerous. The electric healing devices advertised broadcast, as electric belts, etc., are mere swindles and without any value. See ELECTROTHERAPEUTICS.

ELECTRICITY

Prospect.—Only the very beginning has been made in the use of electricity as secondary form of power for transmitting energy from its natural source, waterfall or coal mine, to the place of consumption, factory, city, railway. Here very great strides are still to be looked forward to, resulting in a much more efficient use of the stores of energy afforded by nature. In the production of light from electric energy at present the efficiency is low, due to the use of heat as intermediary form of energy. A direct conversion of electric energy into heat giving an efficiency of 50 per cent or more would make electric lighting many times cheaper than any other form of illumination and so displace all other illuminants. In this direction fair promise of a gradual advance exists. The direct conversion of the stored energy of coal into electric energy and thereby the elimination of the enormous loss of energy between the chemical energy of the coal and the electric energy, is still entirely hopeless and no clue to its solution visible. In electro-chemistry (q.v.), that is the transformation of electric into chemical energy, lies an enormous field which has hardly been touched, although it has already produced powerful industries, as the aluminum and carbide production and therefore holds out the hope of most wonderful advances in the future. See ELECTRO-CHEMICAL INDUSTRIES; METALLURGY; and various other articles in this volume on electrical subjects.

CHARLES P. STEINMETZ,

General Electric Company, Schenectady, N. Y.

Electricity, Animal. See ANIMALS; ANIMALS, MAGNETISM IN.

Electricity, Atmospheric. To determine the analogy between the electric spark as obtained from an electrical machine and the lightning flash, Franklin, in 1752, made use of a kite provided with a pointed rod. This being flown toward the electric cloud, the electricity was drawn through the pointed conductor, led down the hempen string (which was connected by a silk cord wound round a bobbin) to a key, and then passed to a conductor in communication with the ground. Very brilliant sparks could thus be obtained with perfect safety to the experimenter. This experiment of Franklin's was conclusive as to the analogy between atmospheric electricity and the ordinary electric spark. By experiment it has been found that the atmosphere is always more or less charged with electricity. When the sky is clear, it is charged with positive electricity; when lowering or cloudy, sometimes with positive, at other times with negative electricity. From what source or sources does that electricity come? Some physicists have ascribed it to the friction of the air upon the ground, others to the vegetation of plants, and others again to evaporation. It is probable, from modern research, that all the three causes are in operation; the two chief sources, however, are believed to be the vegetation of plants and evaporation. The clouds, then, which float in the atmosphere are more or less charged with electricity; some are charged positively and others negatively. See LIGHTNING.

Electricity, Cause of Death by. The increasing use of electrical industrial currents has brought about conditions of danger to life by which large numbers of people are killed yearly. Statistics regarding deaths caused by

this modern Juggernaut are difficult to obtain, but the evidence seems to show that the number of deaths by electricity would probably reach up into the thousands. As is well known, one of the most important safeguards of the human body against the passage of electrical currents through it is its high degree of resistance. This degree of resistance, however, is subject to a considerable amount of variation. If the skin is dry the resistance is from 5 to 20 times as great as when the skin is wet. From what is known of the amount of electrical current necessary to cause death in man, it is probable that 1,600 volts of electromotive force, of a continuous current, is sufficient to bring about this end, and that an alternating current of half this voltage would probably be fatal. In fact, the general deduction has been drawn from the experiments conducted in electrocution work at the Sing Sing prison, that no human body can withstand an alternating current of 1,500 volts, and 300 has produced death, while for the continuous current it may be necessary that over 3,000 volts may be required to bring about fatal results. Some of the minor injuries due to lightning and electricity are severe burns, paralysis of some of the muscles, deafness, loss of smell and taste, hysterical phenomena, traumatic neuroses. Occasionally blindness has resulted, also insanities of the maniacal type have been known to occur following lightning stroke. As to the cause of death by lightning and electricity, modern research has shown that there are marked changes in the blood vessels, of a hemorrhagic type, and minute alterations in the nerve cells, but these seem to be secondary to the physiological action that the electrical current has upon the fibres of the heart muscle. The electrical shock brings about a condition of delirium or fibrillary contraction of the heart muscle, causing a stoppage of that organ. This theory of the cause of death at present has the largest number of adherents.

As to what can be done for the treatment of electrical shocks, medical science is still somewhat in doubt. For all practical purposes, death, when it takes place, is instantaneous. The evidence derived from non-fatal cases is of great interest. In these, personal experience has shown that a number of individuals who have been rendered unconscious have recognized in the brief moments of consciousness the experience of a strange sensation. Some have even recognized what the character of the sensation was and the general experience has been that this sensation is not painful but is an exaggeration only of the uncomfortable feeling induced by the faradic battery. It seems more than probable that no painful sensations are felt by those who have died. Recoveries from the shock of electricity or lightning which have been severe enough to bring about unconsciousness are very common. As to the border lines which separate the recoverable from the fatal cases it seems difficult to determine. Promptness in the treatment is imperative. External heat to the body, artificial respiration and cardiac stimulants should be used simultaneously. It is of importance to remember that the body of the patient must not be touched by the rescuer with naked hands, but should be dragged away by his clothing, or removed from contact with the earth by slipping a board under him thus to break the connection with the live

ELECTRICITY

wires. Live wires may also be raised by a stick and thus take the body out of the circuit. Artificial respiration (q.v.) by the Sylvester method or by means of the Gibbon's pump should be performed and the body should be surrounded by hot bottles or bricks, and rubbed, and whiskey and other cardiac stimulants utilized. Injections of large quantities of hot salt solution into the rectum may be of service and occasionally it may be necessary to infuse normal salt solution directly into the veins. Efforts at artificial respiration should not be discontinued under from three to six hours.

Consult: Jelliffe, 'Peterson and Haynes Textbook of Legal Medicine and Toxicology.'

Electricity, Contact Theory of, a theory which assumes that the electromotive force of a voltaic cell, and perhaps the electricity produced by friction, is due to the difference of potential assumed by two dissimilar substances when placed in contact.

Electricity, Diffusion of. Electricity diffuses itself on the surface of a conductor. This we may expect from the self-repelling character of the same fluid. An insulated spherical conductor has two hemispherical cups carefully fitted to it, each attached to an insulating handle. The conductor and its covering are charged with electricity, the cups are then removed, and the conductor is brought near an electroscope. No divergence of the leaves occurs, indicating that none of the electricity has passed into the conductor. If the conductor have a spherical shape, the electricity distributes itself equally over the surface; in other words, the density is the same in every part of the surface. We may conceive the electric fluid to surround the conductor as an ocean of equal depth. If the conductor be a brass disk, the electricity is found in greater quantity at the edges or rim. If it be a brass cylinder with rounded ends, the density is greatest at the ends. If the conductor have the shape of a cone, the density is greatest at the apex, and the sharper the apex the greater the density. Hence the remarkable effect of a pointed body in either drawing, or parting with, electricity.

Electricity, Dissipation of. The gradual loss of electricity from a charged body surrounded by non-conductors, which takes place by means of them, is called dissipation of the electric charge. A charged conductor, for instance, supported on a glass pillar, slowly loses its electricity. This is due partly to the creeping of the electricity along the surface of the glass, which even if it be free from dust and dirt, is never absolutely free from an invisible film of moisture; and partly to the air that surrounds the conductor, the particles of air becoming charged and flying off, carrying electricity with them. In performing delicate experiments such as those of Coulomb for determining the laws of the distribution of electricity on conductors, this gradual loss must not be neglected; and accordingly Coulomb made a careful investigation into the laws of dissipation, by which he was able to allow for it in cases where he could not arrange his experiments so as to be undisturbed by it. Coulomb was led by his experiments to abandon the use of glass as a support for his conductors whenever it was possible, employing instead thin

stems of shellac, and sometimes suspending small electrified bodies by well-dried silk fibres. He found that the amount of loss in a given time by means of the particles of air diminishes as the charge possessed by the conductor gets weaker and weaker, the losses in successive equal intervals of time being in geometrical progression.

Electricity, Experimental Researches in, by Michael Faraday (1839-55). A monumental work in the literature of science; not merely recording the results of experiment in what Tyndall called "a career of discovery unparalleled in the history of pure experimental science," but enriching the record with thoughts, and clothing it in many passages in a style worthy of exceptional recognition. In devising and executing experiments for passing beyond the limits of existing knowledge, in a field the most difficult ever attempted by research, Faraday showed a genius, and achieved a success, marking him as a thinker not less than an observer of the first order. In strength and sureness of imagination, penetrating the secrets of force in nature, and putting the finger of exact demonstration upon them, he was a Shakespeare of research, the story of whose work has a permanent interest. He made electricity, in one of its manifestations, explain magnetism. He showed to demonstration that chemical action is purely electrical, and that to electricity the atoms of matter owe those properties which constitute them elements in nature. In language of lofty prophetic conception he more than suggested that the physical secret of living things, the animal and the plant, is electrical. He particularly dwelt on the amount of electricity forming the charge carried by the oxygen of the air, which is the active agent in combustion and the supporter of life in both animals and plants, and only stopped short of definitely pronouncing vitality electrical. He urged very strongly as a belief, to which no test of experiment could be applied, that gravitation is by electrical agency, and that in fact the last word of discovery and demonstration in physics will show that electricity is the universal agency in nature. And among his far-reaching applications of thought guided by new knowledge, was his rejection of the idea of "action at a distance," in the manner of "attraction." If a body is moved, it is not by a mysterious pull, but by a push. The moving force carries it. These ideas outran the power of science to immediately understand and accept. But Maxwell, Hertz, and Helmholtz have led the way after Faraday, to the extent that his electrical explanation of light is now fully accepted. Fifteen years after his death, the greatest of his successors in physics, Helmholtz of Berlin, said in a Faraday lecture in London, that the later advances in electrical science had more than confirmed Faraday's conclusions, and that English science had made a mistake in not accepting them as its point of departure for new research.

Electricity, Frictional. It was an observation made by the Greek philosopher Thales, 600 years before the Christian era, that, when amber was rubbed, it acquired the property of attracting light bodies. The cause of this attractive power was assigned to a principle to which the name of "electricity" was given—

ELECTRICITY

derived from the Greek word for amber. When a piece of wax is rubbed on the coat-sleeve, an attractive power is awakened in it; it is capable of attracting small pieces of light paper or particles of sawdust—a fact well known to every young person. Taking a warm glass tube closed at one end, and rubbing it with silk, the same thing is manifested. It is observed also that after contact with the wax or tube, the light bodies fall away, being seemingly repelled. If a stick of sealing-wax be rubbed with flannel and then balanced on a paper loop suspended by a silk thread and the knuckle be presented to it, the wax will in like manner follow the hand. We have, therefore, the fact that an electrified body attracts or is attracted by an unelectrified body. Another experiment of a simple character may be mentioned. Take a piece of warm brown paper or sheet of foolscap, place it upon a warm board and rub it well over with a piece of india-rubber, it clings to the board; or remove it from the board and apply it to the wall of the room, it adheres to the wall and remains in its position till its electricity is dissipated. See **ELECTRICITY**.

Electricity in Medicine. See **ELECTROTHERAPEUTICS**.

Electricity, Progress of the 19th Century (1800-1900). Before the year 1800, the world's knowledge of electricity was confined to observations on the attraction of electrified pith balls, and to a few facts in regard to electric sparks. Had it not been for lightning, no one could have felt respect for the feeble manifestations of an agency which was destined in less than 100 years to change the channels of trade, to revolutionize methods of communication, and to light the great cities of the world. Lightning was a portent of all this; but no one yet saw the beneficence in the energy that was so destructive and so terrifying. There was another feeble force, too, of which the world in 1800 knew something—the force of magnetic attraction. This was useful in the magnetic compass; but it was judged to be insignificant in other respects and totally unrelated to the force of electrical attraction, which was manifested in the case of the pith balls, or to the forces of lightning. No one in the wildest flight of imagination saw it exalted to a Titanic force, capable, by means of its relationship to electrical attraction, of moving all the machinery of a great city.

The marvelous development of electricity which we have all seen seems to carry with it the presumption that we have a clearer knowledge of what electricity is than Benjamin Franklin had; but this presumption is not entirely warranted. We certainly know its relations to other forms of motion, such as light and heat, better than he did. We believe that it is a wave motion; but still we cannot fully explain the fundamental experiment of the attraction of two electrified pith balls. To the philosopher, this confession of ignorance of an agency which he can use intelligently, which is highly serviceable, but the origin of which is completely veiled from us, is most suggestive. The question immediately arises, "To what do we owe our command of this mysterious servant?" The answer to the question is this: "We owe our advance in knowledge to the careful verification of phenomena, to the improvements in machinery pro-

duced by almost microscopic measurements, and to accurate calculation."

The steps which led to our present knowledge of the manifestations of electricity can be quickly told. The first was taken by Galvani, who, just before the last century dawned, demonstrated that electricity could be produced by the contact of metals with fluids. His experiments suggested to Volta in 1800 the electric battery. Here was a means by which an electric current could be produced; and Oersted with this current showed a connection between electricity and magnetism. The current in passing through a wire near a compass needle could change the reading of the needle, and the changes depended upon the direction in which the current flowed. There seemed to be a suspension and a hush between each of the turning points in the history of the advance of electricity, which are typified by the stillness before a thunderstorm. Oersted's discovery was made about 20 years after Volta constructed his battery. It was more than 10 years after Oersted that Joseph Henry and Michael Faraday discovered another relationship between electricity and magnetism which involved the possibility of producing currents of electricity by the motion of a magnet. This discovery was the converse of Oersted's; the series of phenomena which it revealed embraced the subject of electro-magnetism, and have led directly to the invention of the dynamo and electric motor. The world, however, did not realize in 1831 the importance of the steps taken by Henry and Faraday. Another 10 years elapsed before the electric telegraph became a success. Then in 1861—30 years from the date of the discovery of electro-magnetism—Paccinotti invented the armature which Gramme improved, and we had the dynamo and the electric motor. Again, in a little more than 10 years, the telephone came, and the mechanical engineers and the mechanic, thoroughly aroused to the possibilities in the practical employment of electricity, took hold with astonishing energy.

When Tyndall came to the United States in 1870 to deliver lectures on light and electricity, he brought with him 100 Grove cells to produce an electric light for the purposes of demonstration. His assistant was obliged to spend two hours before each lecture in arranging these cells, filling them with acids and scraping the connections, retiring from each encounter almost asphyxiated by the irritating and poisonous fumes of nitrous oxide gas. At the present time no lecturer on science in the halls where Tyndall spoke need spend a moment in providing a source of electricity. It is on tap, so to speak, and can be obtained by touching a button. Tyndall in his highest flight of scientific imagination did not picture a development of electricity which would light the halls in which he spoke, which would convey him to and fro with great speed through the streets which he used in going to them, and would enable him to whisper from Boston across the great prairies of the West to St. Louis.

The title of his lectures in Boston was suggestive—"Light and Electricity." Yet his imagination, greater than that of most of his contemporaries in science, failed more completely in the subject of light than in the field of the great practical expansion of electricity. He had no inkling of the coming theory that

ELECTRICITY

light is but one of the manifestations of electricity, and in 10 years from the date of his lectures would be so regarded by the leaders of scientific thought. When we reflect upon how much this man saw and how much was withheld from him, a feeling of self-abasement comes over us who are students of electricity. Who can foretell what the next 100 years will unveil?

In reflecting on the rapid advances in the employment of electricity, we are apt to overlook the aid which has been given by the improvements in the mechanic arts. It can be maintained with a great show of reason that the modern lathe, the milling machine, together with the principle of interchangeable parts in machines, have made the dynamo and the electric motor. It is said that Joseph Henry spent months in wrapping wire with cast-off gowns to insulate it for his experimental electro-magnets. Much more powerful magnets can be wound to-day in half an hour. The mechanical means of trying experiments in the practical employment of electricity have multiplied to such an extent that every mechanic can enter a field which once was occupied by only one man in America, Joseph Henry; and can enter it with the most refined appliances in respect to tools and materials. Many of the men who have aided the practical development of electricity have known little of the subject of electricity. Some who have achieved distinction as electricians were ignorant of even elementary laws; but they saw how machines could be operated by what to them was a fluid analogous in its manifestations of flow and pressure to water. Just as men were ingenious in transmitting power by pulleys, belts, and chains, they now became apt in devising circuits, switches, armatures, keys, and the multitude of devices of which one gets a realizing sense in reading the advertisements in the thousand and one papers and periodicals devoted to practical electricity. In a similar manner mariners had become skilful in using the winds, the scientific laws of which they had not studied. The men who have made a lifelong study of electricity are amazed in reading the reports of meetings of electrical engineers to see the photographs of hundreds of men prominent as authorities at such gatherings—men who have suddenly sprung into notice in a field where only college professors once worked. A young man seeking to become an electrical engineer is told to-day, with reason, that he should first become a mechanical engineer. This development of practical electricity through the advancing improvements in machinery will continue, undoubtedly, to be a great characteristic of American industry. The first thought, apparently, of an American mechanic when he looks at a piece of foreign-made electrical apparatus is: "How can I improve it?" He speedily tears it to pieces, puts in screws that are interchangeable, takes out clumsy devices, reduces the weight, removes useless lacquer, and makes a new thing of it—if he does not throw the whole affair on a rubbish heap and proceed to build a machine on an idea which he has grasped.

To the American mechanic, who, having lost his corkscrew, inserts an ordinary screw through a piece of wood in the cork and pulls it, is due much of our national progress in practical electricity. I had occasion lately to buy a modern lathe for the Jefferson Physical Laboratory, and

was surprised to find that I should be obliged to wait several months for its delivery. I was informed that 80 per cent of the products of the mills went to France, and Germany, and that foreign labor working 10 hours a day could not compete with American labor working 8 hours on these improved lathes. There is no need of a duty on foreign machinery, for we can trust to the ingenuity of American mechanics to hold the markets.

The efforts of inventors have been turned to electrical devices to such a degree that one has to wait months for a hearing at the Patent Office, and the examiners are so bewildered, apparently, by the claims that they grant patents in the expectation that litigation will settle points which require special study and training to consider properly. In addition to the honest inventor of electrical apparatus, we have another class, who seek to cover the ground of possible advance and to reap the fruits of subsequent study by patient investigators. They stake out claims and sit down, waiting for the worker. This class is not confined to the rank of inventors. There are sensation mongers who make predictions of what will be accomplished some day in electricity, in the hope that when arduous investigators have reached with almost superhuman patience the heights imagined, the suggesters will receive the rewards and the distinction. This is a phase of the use of the scientific imagination which was characteristic of the close of the 19th century. The workers of the next 100 years will find it hard to achieve all these outlined advances. But if the advances are not in the direction anticipated, there are other paths which the well-trained man will open, and which will lead to yet undiscovered domains richer than any hitherto attained.

We obtain a realizing sense of the importance of the advance in electricity when we reflect what changes it has wrought in the United States. The invention of the telegraph has falsified the predictions and estimates of many political economists. Sidney Smith, writing to Earl Grey after the acquisition of California, said that this marked the end of the great American republic, for a people spread over such a vast area, having such diversified interests, and separated by such natural barriers, could not hold together. He did not foresee how strongly a light iron wire could bind San Francisco to New York. The introduction of the ocean cable destroyed the class of East India merchants who went down to the sea in ships. Salem Harbor, in which great sailing vessels rode at anchor or drew up to busy wharves, is now deserted.

No longer can a merchant take extensive ventures in ships' cargoes, for the state of the market is throbbled every instant round the world. Thus a revolution has been caused in commerce by electricity. It is still progressing. When the invention of the telephone was made, it was a common remark that it could not supersede the telegraph, for the latter gave a merchant some evidence of a business transaction, while the telephone left no sign. Notwithstanding this lack of evidence, many kinds of business are now transacted over the telephone. Cotton, for instance, is bought and sold in immense quantities, without any written record of the transactions; for business honor is found to be essential, and without confidence in buyer and

ELECTRICITY

seller no transactions are possible. Thus electricity may be said to work for morality.

While there has been a remarkable extension in the communication of intelligence over great distances, there has been a no less remarkable one in the application of electricity to the conveyance of people and goods. Electric railroads are intersecting the United States in almost as many directions as the telegraph and telephone wires. One can travel from Boston to New York by means of such roads, and they bring a desirable element of excitement and the possibility of change of scene to the farmers' wives, once isolated on the dreary farms of New England. Here again electricity becomes an important agent in the spiritual as well as the material life of the nation. Electric motors have not yet superseded steam motors on any of the great lines, and there does not seem to be any immediate prospect of the change; for electric power cannot at present be transmitted economically 100 miles, and the electric motor suitable for the long-distance transmission of electrical power has not been sufficiently perfected. The accomplishment of the substitution of the electric motor for the present locomotive is something left over for the present century. When this substitution is made we shall not be troubled with cinders, and forest fires will be less frequent.

The chief source of electricity is coal, and the century just closed gives no hint of a possible rival to coal unless we except water power. There promises to be a great development in the use of waterfalls in places remote from tide-water, wherever the transportation of coal adds greatly to its cost. Thus, in Switzerland, water power from the numerous mountain sources supplies both light and electrical power for varied industries. The great plant at Niagara Falls for the transmission of power is watched with interest, for if electrical power can be economically transmitted from the falls to New York, the calculations in regard to the diminishing coal supply of the world would lose their ominous character—unless the geologist can show that the world is gradually drying up. The transmission of electrical power has led to a centralization of steam power in great cities. The small steam engines which were scattered about in numerous workshops have greatly diminished in number, and their place has been taken by electric motors supplied with current from a central station. In the same way the gas engines, which at one time seemed to be rising in importance, have largely given way to the electric motor. Thus the plans to pipe gas from central gas manufacturing to all parts of a city for power is checked by the extension of a more subtle medium, far more flexible in its applications. No one will use a gas engine if he can obtain an electric motor; for the care and repairs on a gas engine are far more burdensome than in the case of its rival. Moreover, electrical power can be obtained or shut off by merely moving a switch or touching a button. The centralization of power in the physical world seems to be a counterpart of that taking place in the commercial world.

On the great battleships, electric motors are supplanting steam engines and hydraulic engines for moving the turrets, handling the anchors and

the heavy guns. This change in the method of distributing power is one of the most remarkable in the development of industry in this century. Steam is still the great moving agency in the world of industry, and electricity is produced by it. Electricity may also be called its servant, for from a central station it generates and transmits what is like a vital fluid to every part of a great city. Steam is still the master of electricity, and there is no prospect of the economical production of electricity by any other agency. This is still the age of steam and not of electricity. The telegraph, the telephone, the electric light, and the electric motor constitute the great achievements in the practical employment of electricity. Great chemical industries are also being established, in which processes are carried on by electricity—notably the manufacture of aluminum, of calcium carbide, of the alkalis, and of carborundum.

In this brief account of the rapid progress in the practical employment of electricity, I have dwelt largely on the aid that the advances in the mechanic arts have given to the development of this employment. The work, however, of the scholars and theorists must not be overlooked. In 1800 there were the one-fluid and the two-fluid theories of electricity—neither of which is now believed by scientific men, though these theories prevailed till nearly the middle of the century. In 1843 Joule established the doctrine of the conservation of energy, by an exact measurement of the equivalent of heat, and this measurement led to the calculation by scientific men of the electrical units, which have made possible the advances by practical men. Without this system of units, founded strictly on the doctrine of the conservation of energy, and the quantitative transformation of steam power into electrical power, practical men would have floundered and business men would have lost heavily in electrical ventures, the expense of which could not have been calculated. After the establishment of the doctrine of the conservation of energy came Maxwell's great hypothesis of the electro-magnetic theory of light. This theory supposes that all forms of energy—light, heat, and electricity—come to us from the sun in the form of electrical and magnetic waves. On this hypothesis, electricity and magnetism are indissolubly connected. One can be transformed into the other—light and heat are electrical. The only difference between electricity and light is in the length of waves in the ether. The century has closed with this grand generalization, the truth of which the entire scientific world is engaged in testing. There is every prospect that it will form the most fruitful hypothesis in the century before us. The experiments of Hertz, who was the first actually to measure waves of electricity, have greatly strengthened the electro-magnetic theory of light. He showed that most of the phenomena of light waves could be repeated with electric waves. They can be reflected, refracted, and polarized. What explanation, however, can we give, on this hypothesis, of the simple experiment of the attraction or repulsion of two electrified pith balls—the apparently insignificant manifestation of electric force with which the century started? How can electro-magnetic waves explain this? It is, indeed, difficult to do this; and to give a reasonable supposition we have to theorize in regard to the

ELECTRICITY — ELECTRIC LIGHTING

molecular structure of matter, and the tension under which it exists when it is polarized—that is, when a positive and negative state, typified by a positively or negatively charged pith ball, exist in the neighborhood of other objects. Our new knowledge of the relations of electricity to other forms of energy is probably destined to come from a careful study of the fundamental experiments of the attraction of electrified bodies. We have already entered on this study with renewed vigor, stimulated by the discovery of the marvelous effect of the X-rays in penetrating matter and in making gases better conductors of electricity. Thus we start on the new century with investigation of the same phenomena that Benjamin Franklin considered, but with a far wider comprehension of extended relations, with immensely greater experimental resources, and with a well-trained army of investigators. What has been done is small in comparison with what should be done in the next 100 years.

JOHN TROWBRIDGE,
Harvard Professor of Science and Useful Arts.

Electricity, Thermo. If a strip of copper and a strip of bismuth be soldered together, and heat be applied to one of the junctions, a current of electricity is generated, flowing in the direction of the arrow, from the copper to the bismuth. If cold be applied to the junction, the current flows in the opposite direction. The electricity thus evolved is called thermo-electricity.

Electricity, Voltaic, the branch of electric science to which an experiment by Galvani gave birth. His wife, who was making soup from frogs, happened to put them after being skinned in proximity to a charged electrical machine belonging to her husband. On touching them with a scalpel their legs became greatly convulsed. Galvani on his return was told what had occurred, and repeated the experiment on several occasions. He united the lumbar nerves of a dead frog with its crural muscles by a metallic circuit. He came to the erroneous conclusion that animal electricity existed in the nerves and muscles of frogs, etc. In this explanation Galvani ignored the metallic connecting wire. His contemporary, Volta, gave attention to this, and found that the contraction of the limbs is more energetic when the connecting arc is made of two metals instead of one. He therefore inferred that the metals took the active part in producing the contraction, and the disengagement of electricity was due to their contact, and that the animal parts constituted only a conductor, and at the same time a very sensitive electro-scope. In 1793 he published these views, and in 1800 first described and constructed what has since been called after him the voltaic pile. Febroni observing that the disks of zinc in the pile became oxidized in contact with the acidulated water, considered, as did Wollaston and Davy, that the oxidation was the chief cause why electricity was disengaged. Now voltaic piles have nearly given place to voltaic or galvanic batteries. See BATTERY; ELECTRICITY; GALVANI; MAGNETISM; PRIMARY BATTERIES.

Electric-light Bug. See FISH-KILLER.

Electric Lighting. In 1800 Sir Humphry Davy discovered that if two pieces of car-

bon are joined by a conductor to a source of electric current, and such pieces momentarily touched together, so that the circuit is complete, and a flow of current established; upon their separation for a short distance, a flame is emitted, and, if the current be sufficiently powerful, this flame will continue, the carbon points will become intensely hot and emit a brilliant light. In separating the carbon points, the extra potential induced by the self-inductive of the current, is sufficient to leap the small air gap and thereby vaporizes a small quantity of carbon. Carbon vapor being a conductor, allows the current to flow across the gap. The vapor is of high resistance; therefore the vapor is heated to a high temperature. In 1809, Davy exhibited his arc light before the Royal Institute of London, his carbon points being charcoal from the willow, and his source of current a powerful voltaic pile. Such in its essential features is the arc lamp of to-day.

In the phenomena of the direct current between carbons, the current is presumed to flow from the positive to the negative, tearing away the particles of carbon from the positive, and depositing upon the negative electrode. The positive electrode thus becomes hollowed out, and some of the particles becoming deposited upon the negative electrode, it assumes a pointed form. The temperature of this flame of vaporized carbon is very high. In it is the most infusible substances as flint, platinum and diamond melt. The carbon points emit the larger portion of the light, and the positive point more than the negative. The resistance of the arc may vary from 1 to 100 ohms. It requires a current strength of 3 to 10 amperes, and a minimum electromotive-force of 40 to 50 volts to maintain a satisfactory lighting arc.

Davy used wood charcoal for his electrodes. And while they were of excellent quality, on account of their softness, would last only a short time. As the arc would burn away, it was necessary to continually adjust them, or the arc would go out. Therefore, it was found necessary to have carbons of sufficient density to last a reasonable time; and purity so that the light may be steady. Also to have a mechanism to automatically feed the carbons, and keep them a constant distance apart, as well as automatically bring them together in order to start the arc. Refined petroleum coke, ordinary gas coke, or lamp black is now taken for the base material, thoroughly ground and mixed into a stiff paste, dried and carbonized out of contact with the air. A very hard and uniform carbon is thus obtained, in any desired size, the usual length being 12 or 14 inches, and diameter $\frac{1}{8}$, $\frac{3}{8}$, or $\frac{1}{2}$ inch. Broadly, the lamps may be divided into two classes: series and multiple. Each system into two sub-divisions: the open and the enclosed.

The electric energy lost from the point of generation to the lamp may be expressed, $W = C^2R$.

Where W is energy in watts, dissipated as heat in conductors, C is current in amperes, and R is resistance of circuit in ohms.

Therefore, from the equation it is noted, the loss is in proportion to the square of the current, R remaining constant. Therefore, in distributing electric energy to a number of arc lamps, it is more economical to keep the current constant, and have the lamps joined in series.

ELECTRIC LIGHTING

Two types of lamps were evolved to meet these conditions, as well as a generator to keep the current at a constant quantity, (1) the differential lamp; (2) the shunt lamp. In the differential lamp, the current must remain at a constant point. The main current is carried to a pair of lifting magnets, over which, but wound in opposition thereto, is a coil of high resistance, the terminals of which are cut around the arc itself, and called the shunt magnet. When current is thrown into the lamps, the main current pulls the carbons apart until sufficient potential is obtained at the arc to force current through the shunt magnet, which neutralizes the main magnet, thereby securing a balance, and maintaining the potential at the arc constant. In the shunt type lamp, the shunt magnet circuit is so arranged as to trip the clutch holding the carbon rod, thereby allowing the carbons to come together, should the potential around the arc exceed the predetermined amount. This lamp will burn upon any current strength, providing it is enough to operate the main magnet.

The conditions common to both types of series lamps are: (1) As the carbons burn away, they must be fed down gradually and not allow the potential around the arc to exceed a certain amount; usually 51 to 53 volts. (2) Should the carbon rod stick, or anything happen to disarrange the lamp, there will be a protective device or devices usually called cut outs, so the lamp will not be burned up, or the circuit opened.

Since the advent of arc lighting, there have been many forms of lamps evolved, using carbons in all forms. But at the present day all have come to practically the same style and form of lamp, with few modifications.

Multiple Arc Lamps.—Arc lamps may be arranged for multiple burning at 110 or 220 volts: As most cities are provided with low tension, constant potential mains, it is convenient to be able to place arc lamps upon the same system as incandescent and the motors. This style of lamp requires a large amount of copper for a given distribution for the reason given in former formula. The lamp itself is most uneconomical, as the voltage at the arc must be cut down to 50, which is absorbed in a steady resistance at the top of the lamp. The open type of lamp for multiple burning is almost obsolete.

The Enclosed Arc.—The open arc is now being largely superseded by what is called the enclosed arc. It was discovered that if the arc is surrounded by a small air-tight globe, it greatly modified the character of the light, and the carbon would last much longer. The small globe prevents the air from having access to the carbon, thus preventing its oxidation. When the lamp is started, it soon exhausts the oxygen contained in the globe, and if the globe is tight, the carbons will last from 80 to 175 hours. This type of lamp is now used almost exclusively for multiple burning both for alternating and direct current. The voltage at the arc is from 75 to 80 volts, and requires from $3\frac{1}{2}$ to 6 amperes. Upon a constant potential circuit, it is necessary to absorb the difference between 80 and 110 volts with a resistance at the top of the lamp. With the alternating current lamp this reduction is obtained much more economically by means of a reactance which absorbs the excess potential. The enclosed arc is meeting with

considerable success, also on constant current circuits. They usually are operated at five amperes. The great advantage obtained is the small cost of carbons and attention. The light is considered superior to the open arc.

The Incandescent.—The great objection attending the use of the arc system of lighting was that the light was too intense for most purposes required inside. It could not be readily subdivided. From the earliest days of electric lighting, various inventors endeavored to subdivide the light. The idea of using continuous conductors, instead of the discontinuous as in arc lighting, was tried in almost every conceivable form. These conductors were to be heated to a white heat and rendered incandescent by the passage through them of an electric current. The great difficulty arose from the fact that to give useful results, the working temperature of the material was so near its melting point, that any slight increase in the current would destroy the conductor. In 1878 a great improvement was effected in the platinum incandescent lamp, which was obtained in a condition to safely withstand a much greater current strength. The platinum filament was placed in a vacuum, and slowly heated therein. The acclused gases were slowly liberated, and it was discovered that if a high vacuum were maintained and the wire raised to a point just below its melting point, the point of fusion was raised, and the physical characters of the melted was considerably changed. This lamp, however, was never a commercial success.

Various inventors experimented with the platinum lamp, enclosed in a vacuum, but the great improvement was made by the substitution of carbon filaments for platinum. This was done by an American, J. W. Starr, who employed plates inside a glass vessel containing a Torricellian vacuum. Many patents were taken out in all countries for lamps of various types, but none were commercially successful; many, perhaps, for the want of a cheap method of generating the electrical energy, as well as the fault of the lamp itself.

The advent of the first successful incandescent lamp dates from about 1879, when Edison gave us the carbon incandescent lamp, and from that time the growth of the incandescent electric lighting industry has been extremely rapid.

Every incandescent lamp consists of a carbon filament attached to two platinum wires; a glass bulb in which a vacuum is formed, and finally a threaded base attached to the bulb, and designed to hold the lamp in its socket.

The following is in a general way the method by which the lamps are made. The bulbs are blown at the glass factory whence the manufacturers obtain them directly. The first manipulation consists of preparing them for the filament. The nature of the filament varies with different systems. There are three kinds employed. Some (Swan) employ cotton thread; others gelatine or vitrified cellulose (Khotinski Lave-Fox); and others use vegetable fibres (Edison-Siemens). Finally, some employ a natural fibre submitted to a chemical process (Langhans Cruto Seel). Form is given to the filament according to its nature, either by means of a die, or between cylinders, or by cutting it out while in a plastic mass. The fibre thus obtained is transformed into compact carbon by prolonged baking at a high temperature in a crucible or

ELECTRIC LIGHTING

by heating with the electric current itself. To give the filament homogeneity, and the desired resistance, a layer of carbon should be deposited on its surface; this deposit is effected in many ways, which are peculiar to each manufacturer. A very simple method consists in immersing the filament in petroleum, and raising it to a red heat in that liquid. The filament being cut to the desired length, Edison clamps the carbon with platinum wires, and covers the points of attachment with a layer of electrolytic copper, Lave, Fox, and Swan deposit a greater quantity of carbon there, while other manufacturers employ a special cement. Soldering to the carbon tends just now to become more and more employed. The filaments may be fixed in the bulb in two ways; either the two wires are fused into a piece of glass called the budge, which is next fused into the neck of the bulb; or else the wires are fixed separately on the edges of a glass socket, which is then fused into the bulb. A small tube is also fused to the top of the bulb in order to provide for the production of a vacuum. The exhaustion of the lamps takes place by means of mercury pumps. The vacuum obtained, the lamp is tested. Then the luminous intensity, and the resistance when cold are measured. The dimensions of the filaments vary with the luminous intensity of the lamp; they should be proportionately greater as the normal intensity of the lamp is higher. These dimensions depend also upon the specific resistance of the carbonized substance. As to the form of the section of the filament, the circular one is preferable because it presents the minimum resistance for a given surface. In Edison lamps the filaments have a section 0.3 MM by 0.1 MM, and a length when straightened out of 125 MM for 16-candle-power lamps, and 110 MM for those of 10-candle power (Paliz).

The reason for withdrawing the air from the bulb is that if the filament were heated in the air, the oxygen of the air would combine with the carbon causing combustion and consequent destruction. Even enclosed as it is in a vacuum the filament is slowly destroyed by the intense heat at which it is operated. Aside from the advantage named is the fact that there is no heat conducting medium between the filament and the globe, practically all the heat that is emitted being that which radiates from the filament (a small amount is lost by conduction through the leading-in wires). If there were any gas or vapor within the bulb it would conduct additional heat to the glass walls, and also dissipate heat by convection, so that with a given current in a given filament, the temperature of the filament would be reduced, and, therefore, less light would be obtained. The destruction of the filament referred to is not due to combustion because as just explained there is no oxygen left in the bulb. There is a disintegration of the filament by some process that has never been positively identified, or explained, the results being, that impalpable particles of carbon are deposited on the inside surface of the bulb, causing a gradual darkening of the glass, that is readily discernible.

The leading-in wires are made of platinum because that metal has the same coefficient of expansion by heat as that of glass. Were the coefficient different, they would expand more or less, and when heated crack and spoil the vacuum. Carbon is an exception to the general

rule, that almost all conductors increase in resistance when the temperature is raised. Its resistance decreases rapidly with an increase in temperature up to the red point. Thereafter, up to the white, the resistance decreases more slowly. The ordinary filament, when at its working point, has about one half the resistance as when cold. The standard filament gives out a mean illumination of 16-candle power at right angles with the axis of the lamp from base to top.

The power required for the usual 16-candle power standard lamp varies from 50 to 64 watts, depending upon the temperature at which the filament is operated. The higher the temperature of the filament, the higher the efficiency in watts per candle power, and also the shorter will be the life. The life of the filament in this way limits the efficiency of the lamp. The candle power of the incandescent lamp may be greatly increased by simply increasing its filament temperature by the simple expedient of increasing the current, but thereby shortens its life. The increase in candle power is not directly in proportion to the increase in current but considerably above it.

The following table shows roughly the relation between voltage, watts, and candle power for 16-candle-power filaments requiring normally 3.1 and 3.5 watts per candle respectively, and to be worked at 100 volts.

Column A is for 3.1 watts and B for 3½ watts.

Effect of insufficient and excessive voltages upon the candle-power wattage and life of an incandescent lamp filament.

Volts at terminals	Candle power	Watts		Per cent of normal life	
		A	B	A	B
96	12.6	45.5	51.7	220	247
97	13.4	46.5	52.7	179	195
98	14.2	47.5	53.8	146	153
99	15.1	48.5	54.9	121	126
100	16.1	49.6	56.	100	100
101	16.95	50.7	57.2	82	84
102	17.9	51.7	58.4	68	70
103	18.9	52.7	59.5	56	58
104	19.85	53.6	60.5	45	47
105	20.8	54.5	61.4	37	39

The foregoing table shows the importance of maintaining the potential on the terminals of an incandescent lamp at the normal working point. Any slight excess materially shortens its life. As previously stated, the resistance of an incandescent lamp filament is much lower when hot than cold, approximately in the ratio of two to one. That is, the resistance is twice as high cold as when hot when at normal burning temperature. The illumination is rated in candle power, and power consumed in watts per candle measured when the lamp is giving its rated candle power, but this condition is not obtained with any incandescent lamp through a large portion of its active life. When a new lamp is placed in circuit, it will usually give the full candle power or a trifle more at the start, and the candle power will rise to a value from 5 per cent to 11 per cent higher than the rating. It soon, however, begins to fall off with a constant diminution up to the breaking point.

The rise and fall of candle power are due to changes in the structure of the filament. The resistance at first decreases allowing more cur-

ELECTRIC LIGHTING

rent to flow, and consequently higher temperature and more light. This is indicated by the rise of the curve from 16.2 C. P. to 17.3 C. P. during the first 50 hours. Then the diminution of resistance ceases, and is followed by the gradual wasting away of the filament, which causes a gradual increase in resistance, by reducing its cross section. The current thus gradually falling off, taken together with the decreased surface of the filament, and the deposit of carbon upon the globe, causes the fall in candle power indicated. The decrease in candle power is not directly proportional to the decrease in current, thus the energy per candle power increases rapidly after the first few hundred hours.

In addition to the arc and incandescent, we now have also the Nernst lamp, which is of late coming into prominence as a lighting agent, and which has many valuable qualities. The Nernst lamp is the invention of Prof. Walther Nernst of Göttingen University, a leading authority in the chemical world. Prof. Nernst was making experiments as to the principles underlying the efficiency of the Welsbach gas mantle. The exact elements and their proportions of the Welsbach mantle have been more or less of a secret, but it is well-known that certain metallic oxides, such as thorium, yttrium, cerium, zirconium, glucinum, erbium, have entered into their manufacture; probably the first three mentioned being the chief ingredients. These very refractory materials are of a yellowish, or a whitish color. They are non-volatile save at exceptionally high temperatures. Prof. Nernst in his early experiments took certain of these substances, such as magnesia oxide mixed with porcelain, which is a high class insulator when cold, but he found were electrolytes when hot. These are called conductors of the second class, or such chemical substances as are decomposed upon the passage of a direct current.

An infinite amount of experimenting has been done both in America and Europe to find the most suitable substances for these electrolyte filaments, or glowers as they are called.

In order to adapt the principle to commercial lamps, there are many problems to be solved. The Nernst Lamp Company of Pittsburg, Pa., hold the American patents, and have developed a very successful lamp. The lamp consists of units of one or more glowers, each rated at about 50-candle power, and used upon 110 to 220 volt alternating current. The lamp consists of: (1) the glower; (2) the steadying resistance; (3) the heater. The resistance of the glower decreases rapidly when heated, and upon a constant potential circuit would immediately burn up were it not for a resistance of iron wire where resistance increases with the temperature, and which is adjusted to balance the decrease in resistance of the glower. The glower when cold is a non-conductor, and, therefore, must be heated before it will conduct the current. After once started the current will maintain the temperature at the conducting point.

The Nernst Lamp Company have arranged that by surrounding or placing in close proximity thereto to a heater, which consists of a coil of platinum wire so arranged that the current is first switched into the heater, which heats the glower to the conducting point. The heater is then switched out.

On account of the very high temperature of the Nernst lamp glower the efficiency is very high. The light is very pleasing; in color it stands midway between the yellow and red rays of the incandescent carbon lamp, and the violet and blue of the arc lamp. It is, however, so dazzling white it is usually placed in ground glass globes.

The electric arc and incandescent lamps are the most efficient practical transformers of the energy of fuel and water to light, which we have.

The following table gives the mechanical equivalent of the most common lights:

Candles	86	watts	per	candle.
Oil lamp.....	57	"	"	"

Incandescent lamp 16 C. P..	3.5	"	"	"
Arc lamp.....	.8	"	"	"

The eye is affected by waves of the ether whose length are included between .810 Y and .36 Y. All vibrations of a wave length above or below the points named do not effect the eye as light, and are, therefore, useless and represent so much wasted energy.

The quantity, therefore, of energy radiated from a source of light is composed of two parts: (1) the energy affecting the eye, or vibrations between the limits of 360 Y and 760 Y; (2) the vibrations above and below .360 Y and .760 Y, and the total energy expended is $Z = X + Y$.

The ratio $\frac{X}{Z}$ of the energy of the luminous radiators to that of the totality is called the optical efficiency of the source. There are two methods used in securing this efficiency: First, passing the rays emitted by the source successfully through a layer of bisulphide of carbon, which allows all rays to pass, and through an equal layer of alum solution, which allows only luminous rays to pass. The intensity of the radiators is measured by a thermo-electric pile. The second method, which is of great exactness, can be only employed for incandescent lamps. The lamp is placed in a calorimeter with the blackened copper sides filled with water. The whole of the heat radiated is absorbed by the water and metallic sides of the calorimeter. The elevation of temperature of the water is then measured in unit of time. The calorimeter is then replaced by one of thin glass, which in this case, absorbs the obscure rays alone. It is said by this method an exactness of .3 per cent is easily obtained (Paliz).

The following table shows the results obtained by various authorities upon the optical efficiency of various sources of light:

Mechanical Equivalent of Light.

1 — candle power — { .2713 watt.
12 foot lbs. per minute.
(Stillman) { 720 foot lbs. per hour.

The low value of the common radiants is due to the fact that they are based upon the incandescence of carbon. We have made immense strides in the cheap production of electricity, but the advance in the transformation of the electric energy to light has not been so rapid. From the transformation of the energy of the coal to light through the medium of the furnace, steam boiler, and engine to electricity and to light, the greatest loss occurs in the last transformation, as the following example will show:

The ordinary steam boiler and furnace, when intelligently operated absorbs from 70 to 80 per cent of the heat energy of the coal, and in a modern triple expansion condensing engine will give or transform 15 per cent of the energy in the steam to mechanical, and in ordinary good practice will run from 2 to 3 pounds of coal per horsepower hour. The electrical generator will transform at 92 to 93 per cent of the mechanical to electrical, and this will be delivered to consumers at 95 per cent, or a loss of 5 per cent.

We, therefore, will have delivered to the consumer approximately 10 per cent of the theoretical energy of the coal. If the conversion to light is through the medium of the incandescent lamp, we will throw away 95 per cent of this energy, and secure as light only $\frac{10}{100}$ or practically 1 per cent of the energy of the coal. Such are the extravagant methods of the 20th century in spite of our boasted progress.

ELECTRIC LIGHTING COMMERCIALY.

A perfect light should possess the following qualities:

Purity.—It should not consume or pollute the air.

Brightness.—It should be soft and brilliant.

Cleanliness.—It should be harmless to furniture, books, pictures and decorations.

Coolness.—As it is light, and not heat that is required, the less heat given off the nearer the light will approach perfection.

Convenience.—It must be readily available whenever required, and should be unaffected by draughts.

Easy Distribution.—It must be available wherever and in whatever quantity desired.

Safety.—It should be free from all risk of fire.

How far do the present illuminants, namely, gas, oil, and candles, comply with the foregoing conditions?

The following table shows the oxygen consumed, carbonic acid produced and air vibrated by the combustion of certain bodies producing the light of 12 standard candles each burning 120 grains per hour.

Light Producing Material Equal to 12 Standard Candles	Cubic Feet Oxygen Consumed	Cubic Feet Air Consumed	Cubic Feet Carbon Acid Produced	Cubic Feet Air Vitrated	Heat, lbs. of Water Raised 10° F.
Cannel Gas....	3.30	16.50	2.01	217.50	195.
Common Gas....	5.45	17.25	3.21	348.25	278.6

Electric	None	None	None	None	13.8

LIGHTING BY GAS.

Purity.—It is not pure, as it both consumes and pollutes the air. Each 12-candle-power gas burner consumes $5\frac{1}{2}$ cubic feet of oxygen, and liberates 350 cubic feet of CO₂ per hour.

Coolness.—It is not cool—the heat produced in one hour by a single ordinary gas jet being sufficient to raise 280 pounds of water 10° F.

Cleanliness.—It is not clean—each 12-candle-power jet giving 3.2 cubic feet of carbonic acid gas per hour in addition to sulphur fumes, which will blacken silver. It also gives off a considerable amount of soot, the evidence of which is soon seen in blackened ceilings, cornices, discolored wall paper, etc.

Convenience.—It fairly meets this requirement, being available wherever required, but fails in so far that it cannot be lighted without another agent, the aid of a match or taper. It is also affected by draughts, causing it to flicker and smoke, while the unequal light is injurious to the eyesight.

Easy Distribution.—The fact that owing to the great heat it gives off, it is not safe to place it near any inflammable substance, necessitates its being in the center of the room at a considerable distance from the ceiling.

Danger.—Scarcely a day passes without some published account of terrible explosions causing loss of life and property. Gas, therefore, fails to fulfil the conditions of a perfect light. Oil lamps and candles fail entirely, and for such obvious reasons they are scarcely worth enumeration.

In the electric incandescent light, however, we find the almost perfect light.

Purity.—It is absolutely pure, there being no consumption, nor pollution of either air or oxygen. There are no waste products of any sort, and, therefore, no smell.

Brightness.—The incandescent light is white, soft and brilliant, but not necessarily dazzling.

Beauty.—An incandescent lamp being in itself a beautiful object requires no external decoration.

Cleanliness.—It is perfect in this respect, no smoke, soot or fumes of any sort being given off.

Coolness.—For the same light heat given off

ELECTRIC LOCOMOTIVE — ELECTRIC PIANO

is one twentieth that given off by gas, and about one fortieth that given off by tallow candles.

Convenience.—It is readily available whenever required. The lamps can be placed in any position, pointing upward, downward or horizontally. It can be placed close to the most combustible substances. It is lighted without match or taper. A room can be lighted by a movement of the finger before entering, and left in darkness by the same movement on leaving it. A passage can be lighted in front of you as you go along, and the light extinguished behind you as you proceed. It is perfectly unaffected by draughts, and will burn, if required, under water.

Safety.—There is no danger in connection with electric light if the work is put in the hands of firms of standing repute. Matches and tapers are not used, and there is no liability of asphyxiation, or explosion like gas.

The electric incandescent light is, therefore, the most perfect light we have for purity, brightness, cleanliness, coolness, convenience, easy distribution and safety. **WALTER H. JOHNSON,**
President Edison Company of America.

Electric Locomotive. See **TRACTION, ELECTRICAL.**

Electric Log, an electric circuit through the log-line to the detent of an escapement in the register-log, so that by touching a key on deck a circuit may be completed, an armature attracted, and thus the starting and stopping of the mechanical register in the log be exactly timed.

Electric Loom, electricity used as the motive power for a loom. In 1852, an electric loom was exhibited by Bonelli at Turin. The invention was at that time in a crude state, but has since been much improved. The object is to dispense with the perforated cards required in the Jacquard apparatus. See **LOOM.**

Electric Machine, a machine for exciting electricity by means of friction. Its inventor was Otto von Guericke, of Magdeburg, who made one, consisting of a sulphur globe, about 1647, following it by the air-pump about 1650. Sulphur was next exchanged for resin, which in turn was superseded by a glass cylinder. Von Guericke's "rubber" to excite electricity had been simply his hand. Instead of the hand Winckler, in 1740, introduced cushions of horsehair stuffed with silk. Bose, about the same date, collected the electricity on an insulated cylinder of tin plate. Ramsden, in 1760, replaced the glass cylinder by a circular glass plate. The glass is rotated between the surfaces of the rubbers, and the electricity which is generated passes to the conductors on each edge of the disk, thence to the prime conductor, and finally to a Leyden jar, or other object, as may be desired. By friction with the glass, the glass becomes positively and the rubbers negatively electrified. The latter communicate with the ground by means of a chain, which carries off the negative electricity as soon as it is produced. In Nairne's machine there is a cylinder which is rubbed by only one cushion. Armstrong's is a hydro-electrical machine. In Holtz's the electricity is not developed by friction, but is induced by the constant influence of an already electrified body. It is an old invention revived and improved, and the

principle has been carried still further by the admirable machines of Voss and Wimshurst. All dynamo-electric machines or generators, whatever their peculiar forms, as distinct one from the other, are based upon the discoveries of Faraday, and Henry contemporaneously in 1832, that if a closed wire or conducting ring is moved across a magnetic space, a current of electricity is generated in the wire. A dynamo-electric generator is the best apparatus devised for the application of this principle to the production of an electric current. A magnetic space is provided between the poles of two or more powerful magnets, and coils of wire are caused to traverse this magnetic space in such a way as to excite a current in them. The stronger the magnetism of the space, the longer the wire and the quicker it is moved, the stronger will be the current excited. See **DYNAMO**; **ELECTRICITY.**

Electric-magnetic Machine. There have been constructed a number of machines for the development of electricity by magnetism. These are termed "magneto-electric machines," and are largely used by the medical profession. In some machines it is desirable to have a continuous flow of electricity. To accomplish this what is called a "commutator" is used. This is an arrangement by which at the proper moment the contrary current is made to flow in the same direction as the other. See **ELECTROTHERAPEUTICS.**

Electric Microphone, an instrument that depends for its action on the extreme sensitiveness of mercurized carbon to the passage of electricity. The feeblest tremors or vibrations of the sound-board affect the carbon pencil and make it vibrate in its sockets. This causes a variable flow in the electric current, by which also a variable effect is produced on the magnet in the telephone. The disk is thus made to partake of the same vibrations as originally proceeded from the sound-board. From the character of the instrument in the way of revealing feeble sounds, it has been applied with success by medical men and physiologists toward detecting any derangement in the functions of the body. See **ELECTROTHERAPEUTICS.**

Electric Motor, a machine by which electrical energy supplied from an external source is converted into mechanical energy. See **DYNAMO**; **ELECTRICITY.**

Electric Navigation. Vessels of small draft are now propelled by electricity. The power drives a motor, which actuates a screw propeller. The current is generally supplied by a storage battery. From their noiselessness electric boats are peculiarly available for nocturnal torpedo operations, and the universal equipment of modern warships with electric lighting and power plants makes their use possible at all points. This type is often termed an electric launch, and most or all electric boats fall under this category. See **ELECTRIC STORAGE BATTERY.**

Electric Organ. See **ORGAN.**

Electric Pendulum, a form of electroscope consisting of a pith-ball suspended by a non-conducting thread.

Electric Railroad. See **TRACTION, ELECTRICAL**.

Electric Railroad Block Signals. See **ELECTRIC SIGNALING**.

Electric Repulsion, the mutual tendency of similarly electrified bodies, or similar electric charges, to repel one another.

Electrics and Non-electrics. The chief work of the earliest experimenters in electricity was to divide bodies into electrics, which they could excite by friction, like amber (Greek amber); and non-electrics, such as the metals, which they could not so excite. These names were given to the two classes by Gilbert of Colchester (1600). But Du Fay (1733-45) showed that electrics are identical with non-conductors, and non-electrics with conductors; and that the reason why non-electrics did not exhibit excitement by friction was that the electricity was conducted away from them as fast as it was produced. The distinction was thus broken down. See **ELECTRICITY**.

Electric Signaling. While it is true in a broad sense that any method of communicating intelligence to a distance is embraced in the term telegraphy, in the present instance the term electric signaling will be employed to cover the signaling systems and methods described in this article. This term is perhaps the more appropriate inasmuch as certain of the systems to be outlined in reality partake more of the nature of mere signals than of a means of transmitting intelligence as that term is generally understood. Almost without exception electro-magnetism is employed in the operation of electric signals. See **ELECTRO-MAGNETISM**.

The Electric Door Bell.—This is perhaps the best known and one of the simplest methods of electric signaling. In its operation it employs a primary battery, a push button at the door, a vibrating bell within the house, and a wire connecting the push button and the bell. The bell and its armature, the connecting wire, the push button and the battery comprise the electric circuit. The push button is merely a key consisting of two strips of metal which when pressed together allows the current to flow. The electric bell consists of a coil of wire wound around a soft iron core. Its armature carries at its free end a small hammer which, when the armature is attracted, strikes against a small gong, ringing it. The vibration of the hammer is brought about by a very simple device. Normally the armature rests against a contact point which is a part of the circuit; the armature itself also being a part of the circuit. The circuit is normally open at the push button. When this button is pressed the circuit is closed and the armature of the bell is forthwith attracted, its hammer striking the gong at that instant. In the act of moving forward, however, the armature leaves the contact point against which it had been resting, with the result that the circuit is opened at that point. This has the effect of permitting the iron of the bell to lose its magnetism, whereupon the armature falls upon its contact point, again closing the circuit with the result that the armature is again attracted, which

action is continuously repeated so long as the push button is pressed in. A small spiral or tension spring suffices to keep the push button normally open.

Annunciator Signals.—The "annunciator" or call-bell systems so generally used in hotels and offices utilize the principle of the door bell. Annunciator systems in fact might be termed multiple electric door-bell systems. Usually a wire runs from each room to a central point or office where the annunciator is placed. This annunciator contains within its case a small electro-magnet for each room. One battery is caused to supply the current for all the circuits by simply connecting the wire from each room to the terminals of the battery. In a similar way one bell at the annunciator is caused to respond to all the calls that come. The armature of each electro-magnet within the case carries a small shutter, on which is placed the number or letter of the room with which it is connected. This shutter is held out of sight by means of a small catch hook attached to the armature of the magnet until the push-button in a given room is pressed, whereupon the armature is attracted, releasing the shutter, which instantly drops, showing the number. At the same time the annunciator bell rings, directing the attention of the clerk to the call. In other forms of annunciators the falling of the armature is caused to deflect a small arrow on the face of the case, beneath where is marked the number, name or letter of the room. There may be almost any number of rooms from 1 up to 100 or more connected with one annunciator. In practice one wire is usually run from the battery and annunciator to each room. This is called the "common return" wire. A separate wire, as stated, in addition is run from each room from the common return wire through the push button to the electro-magnet in the annunciator, thereby supplying a separate circuit for each room.

Burglar Alarm Signals.—For simple domestic purposes the arrangement employed for burglar alarm signals is also closely akin to the systems just described, the main difference being that the finger push-button is replaced by a circuit closing contact in the frame of a window or the jamb of a door. To bring about the result desired the circuit closer is placed on the frame of the window in such a way that the movable portion of the circuit closer projects beyond the surface of the window frame. The contacts of the circuit closer are held apart normally by a simple spring. In order that when the window is closed this projection may not be depressed, a piece is cut out off the window sash at a point directly opposite the projecting circuit closer. In an analogous manner the circuit closer is attached to a door jamb. The wires leading to the circuit closer are concealed behind the woodwork. When a window is raised or a door is opened by an intruder the contact points of the circuit closer are brought together whereupon the annunciator bell is rung, giving the alarm, and at the same time the room where the door or window has been opened is indicated by the dropping of the corresponding shutter in the annunciator. The annunciator is located in any desired part of the house, usually in a bedroom. The method described is termed an open circuit method. In such systems what is known as open circuit batteries,

ELECTRIC SIGNALING

such as the ordinary dry batteries, or the wet Leclanché batteries may be used. In some cases, to guard against a momentary opening of a door or window, such as would only occasion a short ring of the alarm bell, not sufficient perhaps to arouse a sleeper, an auxiliary arrangement is provided at the annunciator consisting of a drop arranged to close the bell circuit continuously until the drop is re-set. A small switch is provided near the annunciator by means of which the alarm circuit may be opened during the day-time so that needless alarm may not be given by the ordinary opening of windows. Other switches are also used for the purpose of testing the various circuits to see that they are in proper working condition.

Central Office Burglar Alarm System.—This system, as the name implies, relates to one in which the ringing of an electro-magnet alarm in a central office will announce the presence of intruders in the building or buildings in which the protecting apparatus is installed. The central office may be any convenient distance from the protected buildings. These systems are frequently termed electric protective systems. The plan usually adopted is to run a net-work of wires through partitions, across floors, skylights, etc. These wires are part of a circuit extending to the central office, and the said wires are so connected with the circuit that any interference with them, after they have been "set," will cut out a high resistance, consisting of a coil of wire, suitably placed in the circuit of the protected building. The cutting out or short-circuiting of this resistance will so increase the strength of the current in the circuit as to operate a "double-balanced" instrument in the central office. If on the other hand the resistance is not "cut out," but instead the wires of the circuit be cut or broken, by accident or design on the part of intruders, the consequent absence of current, or even a slight decrease of current, will likewise cause an alarm in the central station. The double-balanced instrument at the central office is usually a relay, the armature of which carries a needle that normally stands at a zero point, from which point it may be deflected in either direction. An increase of current on the circuit deflects it in one direction—a decrease of current allows a spring or weight to deflect it in the other direction. In either case the alarm is given when the needle moves and an attendant is despatched to the premises from which the alarm has emanated. Each relay is of course suitably numbered or otherwise designated in the central office so that the building with which it is connected is known.

Telegraph Message Service or Emergency Signals.—This service relates to the supplying or calling of messengers, policemen, firemen, etc., at the call of or by a "subscriber," in whose house or office a "call box" has been placed. This call box is electrically connected by means of a wire with a central office at which the messengers are located, and from which office communication with police and fire headquarters can quickly be made. Each call box is numbered and is supplied with what are termed "make and break" attachments which are set in operation by the turning of a crank on the cover of the box. These attachments, when thus operated, transmit automatically to the

central office the number of the box, which at once indicates to that office the location of the signaling box. The construction and operation of the call box are as follows: A crank is mounted rigidly with a recoil spring on a shaft. On this shaft is also mounted, but loosely, a cog-wheel. A "break-wheel," having a number of slots in its periphery, is geared with the cog-wheel in such a manner that it receives a tendency to turn in a given direction, but it is normally prevented from turning by the engagement of a pin on its side with a curved cam which is attached to a prolongation of the crank arm. When, however, the crank lever is turned to, say the right preparatory to sending in a call, the cam is automatically moved out of the path of the said pin and the break-wheel is then free to move. By a suitable pawl and ratchet, the cog-wheel is prevented from moving when the crank is turned to the right. The effect of turning the crank is to wind the recoil spring. When the crank is let go the spring unwinds and turns with it the break-wheel which completes a revolution; at the end of which it is again held by the pin as before. The break-wheel is made part of the circuit leading from the box to the central office. A flat metal spring which is also part of the said circuit rests on the periphery of the break-wheel in such a manner that when the wheel is making its revolution the spring falls into the slots on the said periphery and opens the circuit as many times as there are slots provided. If, for instance, the number of a given box is 24, there will be cut on the periphery two slots in close succession, then an interval of unbroken metal surface followed by four slots in succession. The circuit in such a case, as the wheel rotates, will be opened twice in succession, closed for an interval, and then opened four times in succession, with the result that a bell at the central office will give out, first two strokes, and then four strokes, on its gong. A large number of such boxes can be placed on one circuit without causing confusion. The call box just described suffices to send in a swift call for a messenger. When it is desired to make it possible to call a policeman, doctor or fireman by the same type of box, it is provided with a "stop" that projects through the cover in such a way that the crank cannot be moved beyond a certain point. The ordinary position of the "stop" would be at the messenger call, in which case the number of the box only would be sent in when the crank is turned. If, however, a doctor should be desired, the stop is moved to a point marked "doctor," on the cover of the box and in turning the crank it is moved up to that point. This farther movement of the crank has the effect of bringing into operation one or more additional slots on the periphery of the break-wheel in consequence of which the box number is preceded by one or more single strokes on the bell, which indicate to the central office attendant that a doctor, fireman or policeman, as the case may be, is desired.

Fire Alarm Telegraph Signals.—The importance of electricity as a time saver in announcing the existence of a fire can scarcely be overestimated. A special feature of the electric fire-alarm system is that it not only gives the alarm, but also indicates to the firemen the location of the fire, or within a very short distance thereof. It may be noted that a simple fire alarm system is

ELECTRIC SIGNALING

in many respects similar to the systems just described, in that it consists of a central office or station in which alarm apparatus and battery are located, and of signal boxes in the street and elsewhere by which to transmit alarms to the central office. A wire connects the central station with the various signal boxes in the streets and fire-engine stations. In each signal box is placed a break-wheel, practically similar to that used in the call-boxes of the district messenger or emergency service; the main difference being that owing to the more exposed position of the fire alarm boxes, and their greater relative importance, more substantial boxes are employed. In general these signal boxes are supplied with an inner and outer door to protect the apparatus from the elements. The signal boxes are provided with a crank or a hook which on being operated causes an alarm to be sent to the central station giving the number of the box from which the call has emanated. The signal box is also provided with a small electric gong, which rings each time the circuit is opened. This intimates to the one sending in the alarm that the alarm is being properly transmitted. It also serves the purpose of intimating to any one who might open an adjacent box to send in an alarm therefrom, that the alarm is already being sent, thus preventing interference. At the central station and the various fire stations a gong is struck a number of times corresponding with the number of the box from which the alarm emanates. In the same circuit also an ink-recording register in the central office marks on a paper strip the number of the signaling box, thus giving a permanent record of such alarm. Inasmuch as it is not good practice to put more than 25 or 30 signal boxes on one circuit, but yet is very important that all the fire stations in a given district should receive the alarm, a repeating device is utilized at the central station which receives the alarm from any one of the circuits and thereupon repeats it automatically to all the other circuits.

Automatic Fire Alarm Signals.—In many of the large cities of the United States an auxiliary to the regular fire alarm system, consisting of some form of thermostat included in a circuit in the building to be protected, is employed. This system again is somewhat analogous to the messenger telegraph system described, the chief difference being that in the one case the signal box is manually operated, while in the other case an increase of temperature, due to fire, by affecting the thermostat causes the alarm to be transmitted. Thermostats are of different types. One type consists of a crescent-shaped spring, made up of two strips of metal, steel and copper, one over the other. One end of the spring or strips is fastened to a support, the other end is adjacent to a contact point of an electric circuit. As the metals named do not expand equally under increased temperature the spring as a whole bends when the temperature increases, and the movable end makes connection with the contact, thereby closing the alarm circuit with the result desired. Other types of thermostats are made of easily fusible alloys. Still another form of thermostat consists of a drum-shaped box, holding substances which have a high expansion under increased temperature. The expansion causes the ends of the box to bulge, thereby closing an alarm circuit.

Police Electric Signals.—These may be considered as more or less amplified fire alarm systems, consisting as they do of signal boxes placed on poles and in booths along the routes of the policemen; from which boxes signals of all kinds may be transmitted to and from police headquarters. The signal boxes are connected by a suitable wire with headquarters; and each box has a break wheel, carrying the number of the box. A telephone outfit is also placed in the box by means of which the policemen may converse with the main station. In fact the telephone is used nearly exclusively, the policeman as he arrives at a signal box sending in a signal which intimates to the attendant at headquarters the number of the box at which he has arrived in the course of his beat, whereupon the attendant communicates with the policeman and takes his number, thus getting a record of his whereabouts. If the officer desires to send in a special signal of any kind, as for an ambulance or wagon, or for assistance, he can do so by a special arrangement within the box. In some cities certain citizens are supplied with keys of the signal boxes. Such citizens are authorized to send in signals for police assistance in cases of emergency, and thus the police force is practically augmented by a volunteer service.

Railway Electric Block Signals.—A block system in brief consists of a means of showing manually or automatically certain signals which indicate to the engineer of a train that a certain portion or section of the track before him is "clear" or occupied. The road is divided into sections or blocks which are of various lengths depending in a great measure on the topography of the route, and the amount of traffic. The length of a block varies from 600 feet to several miles. The signals employed in a "block" are either "safety," "caution," or "danger," represented by a white light or sign, a green light or sign, and a red light or sign, respectively. The sign usually consists of the well-known semaphore arm. In automatic electric systems the circuits and apparatus are generally so arranged that the entrance of a train to a "block" sets the danger signal and that signal is displayed until the train passes out of that block into the next, when the danger signal is lowered and the caution signal is shown. When the train passes into a second block ahead the caution signal is lowered and safety is shown. The part assigned to electricity in the operation of these signals consists generally of actuating electro-magnets which are placed in circuits capable of being opened, closed or short-circuited by the signal or car wheels of a train, which electro-magnets are caused directly or indirectly to operate the various signals. In what is known as the Union Switch and Signal Block system, the semaphores are operated against gravity or a counterpoise by compressed air. This air is compressed by a compressor and is conveyed along the track in an iron pipe. A cylinder and piston are suitably arranged on each semaphore pole, the piston being attached to the semaphore arm in such a way that it may operate the arm as the piston rises and falls. The compressed air is let into the cylinder by valves under control of electro-magnets, which in turn are controlled by the track circuits, the latter, as stated, being controlled by the car wheels of a train. The compressed air effects the downward movement of the semaphores against the weight of a counter-

ELECTRIC SMELTING—ELECTRIC STORAGE BATTERY

poise. At this time the signal is at safety. If therefore the air supply fails or the electric apparatus or valves in any way become inoperative, the counterpoise brings the semaphore to the danger position. Another electric block system, known as the Hall Railway Signal System, uses a disk enclosed in a drum-shaped box on the top of a pole. This disk is operated by an electromagnet, the latter being attracted by an electric current which is under control of the engine, the latter operating, as it passes, a heavy current closer by the side of the track. There is one of these current closers at the beginning and end of a block. The engine thus sets the signal to danger as it comes into a block and sets it at clear as it leaves the block. In the more recent installations of electric block systems the semaphores are operated by electric motors contained in the base of the semaphore pole. These motors do away with the need of compressed air. A device named the Miller Cab signal is different from the foregoing systems. It consists of suitable apparatus and battery for operating certain electric lights in the engine cab. Normally a white light is burning, but when there is another train on the block in which the train enters, the circuits are so operated that the white light is cut out of the circuit and a red light is lit up in its place. This of course notifies the engineer of the near proximity of another train.

For a more detailed and illustrated account of the foregoing systems, the reader may be referred to the author's 'American Telegraphy and Encyclopædia of the Telegraph.'

Electric Smelting. See METALLURGY.

Electric Storage Battery, The. The principle of the electric storage battery was known as far back as 1801, for in that year Gautherot discovered the secondary current obtained from a cell which consisted of two silver or platinum electrodes immersed in a common salt solution. He first charged the cell by passing a current through it; then breaking the charging current, he connected the two plates to the terminals of a galvanometer and obtained a momentary deflection, indicating a flow of current in the reverse direction to the original charging current. This, then, may be said to have been the discovery of the principle of the storage battery, but it was nothing more, since 41 years elapsed before anything noteworthy, more, was done toward its development. In 1842, however, Sir William Grove constructed his famous gas battery, which was a long step ahead in the direction of a commercial accumulator. Grove's battery consisted of a pair of platinum strips immersed in dilute sulphuric acid, each strip surrounded on the top and sides by a closed glass tube which collected the gas developed in charge, and kept each gas in contact both with its respective electrode, and with some of the adjoining acid surface. If this apparatus, after having current passed through it for some time, be connected to a galvanometer, it will yield a small current in the reverse direction for a considerable time, or until the oxygen and hydrogen developed by the charge have gradually become absorbed by the platinum and have recombined to form water. It will be seen that this cell was a very great advance over the experiment of Gautherot, but

yet it was absolutely without practical value as a storage battery, and a great deal of thought and labor expended since Grove's time have failed to further develop it.

It remained for one Gaston Planté, a Frenchman, in 1860, to make the one more important step which immediately demonstrated the wonderful possibilities of the storage battery, and which set other inventors to work all over the world. His experiment consisted in making a cell which had lead strips immersed in dilute sulphuric acid instead of platinum, as was used by Gautherot; this cell being charged by a current would yield a very considerable reverse or "secondary" current. Planté's important discovery, however, was that each time such a cell was charged and discharged the amount of the secondary current, or the "capacity," of the cell increased; and further experiments showed that by not merely discharging the cell but by charging it up in the reverse direction each time, the capacity was brought up even more rapidly. Planté was thus enabled to make secondary cells having enough capacity to give them great commercial importance, and since the changes and improvements which have been introduced since his time are all directly along the same lines and all involve the same fundamental principles, it is eminently fitting and proper that to Planté has been attributed the honor of inventing the storage battery. Examining his results carefully, Planté found that the lead plate which was connected to the carbon or negative pole of the primary battery, became coated with a film of dark brown peroxide of lead, and the lead plate connected to the zinc terminal of his primary cell was coated with spongy metallic lead. Each time the current in the secondary cell was reversed a little more of the solid metallic lead of the plate became peroxidized, and the gradual accumulation of this film of "active material" on both plates, caused the increase in capacity. Planté arranged a large series of cells through which he continually passed a current, first in one direction, then in the other, the duration of the charges gradually increasing, and by this treatment, in course of time, his plates accumulated a considerable thickness of active porous lead and lead peroxide upon their respective surfaces, and after one or two months of the treatment (which he called formation) were ready to be used. It will readily be seen that this forming process for converting the solid lead into active material was very troublesome and expensive, and it was in overcoming this difficulty that the next great step ahead was taken. While Planté's batteries might have been of great commercial value, the very limited use of electricity at that time necessarily curtailed its usefulness very much, and it was not until the development of the dynamo that the real need for a storage battery was felt. It was in response to this need that Camille A. Faure, in 1881, patented a method for making storage batteries, by which the long forming process of Planté was entirely obviated. Instead of chemically attacking the surface of the metallic lead plate, Faure covered the surface with lead oxide in the first instance. A single charge then was sufficient to convert this into lead peroxide upon the one plate and metallic lead upon the other. This invention, which is virtually the last great stride toward the perfection of the storage bat-

ELECTRIC STORAGE BATTERY

tery, is commonly credited to Faure, but incorrectly so, since Charles F. Brush, in America, working independently of Faure, arrived at the same principle at almost the same time, so that in this country priority was given to him, and it is Brush's patent which has ever since controlled the so-called "pasted" plate throughout the United States. All battery plates made to this day are either after the Planté type, where part of the metallic lead plate is chemically acted upon to produce the active material, or else after the Faure-Brush, or pasted type, where the active material, usually in the form of an oxide of lead, forms an integral part of the original plate. It must not be understood from this that no improvements have been made in recent years, but rather that each improvement taken singly has been of relatively small importance, and that the vast number of these, and the constant perfection of detail, have collectively made an immense difference to its practical performance.

a few years' experience it was found that neither of these two expedients was sufficient for practical purposes, and many inventors set to work to construct grids which would effectively retain the active material, and particularly the lead peroxide upon the positive plates. The number of different forms of grid thus brought out almost surpasses belief, and a few only of the most important are here illustrated (Figs. 1 to 9).

These examples, selected from among the types of pasted plates which have been most successful, show the general tendency toward that construction of grid which will have the best grip upon the active material and which will make it as difficult as possible for the latter either to lose electrical contact with the grid or to fall to the bottom of the cell. In some cases, as the Tudor plates illustrated, the grids after being cast have been passed through rolls which turn over a part of each fin so as to give it a grip on the material; in other cases the grids

FIG. 4.—Bradbury & Stone.

FIG. 5.—Hagen.

FIG. 6.—Tudor.

Figs. 1 to 12 are types of grid for pasted plates. Shaded portions represent lead, unshaded portions active material.

Some of these refinements of design and detail are as follows :

Faure's original plates consisted of plain sheets of lead, sometimes roughened on the surface, upon which was spread or pasted the lead oxide intended to become active material. It was soon found, however, that in practice this arrangement was entirely inadequate, since the lead peroxide on the positive plate quickly lost its hold upon the supporting sheet and fell away from it.

In order to meet this difficulty, Swan, in England, and Brush, in America, at about the same time, devised a variety of grid plates, whose object was to provide means of locking the material fast. These grids were either like a flat plate with a number of deep grooves extending into its surface (Fig. 2), or else like a flat plate having a number of holes entirely through it (Fig. 3); the lead oxide intended to become active material being worked into the openings in either case and there held by the large surface of contact with the grid. But with

have been cast with holes bigger in the middle section than at either surface; and in still others, notably the chloride plate, the active material made into small blocks has been placed in the mold and the lead grid cast around it. Finally in the latest type of pasted plate two grids, each having a perforated sheet of lead cast on one side are riveted together with the sheet of lead on the outside, thus forming a number of completely enclosed pockets which hold the active material (Fig. 9).

Quite soon after the storage battery came into extensive use it began to be found that in spite of all possible precautions in the design of the grids, the peroxide of lead on the positive plates would always become soft on the surface and would gradually wash away, leaving the empty grid with little or no capacity. This inherent defect of the pasted positive led manufacturers to seek a remedy in the older or Planté type for their positives, and in this they were so successful that except for small batteries for automobiles and some few other cases

ELECTRIC STORAGE BATTERY

where lightness is a great factor, the Planté type of positive is now always used. Its advantages consist in the facts that, (1) the peroxide being a very thin layer and very close grained, and also being protected from the wash of the electrolyte by reason of its location in the grooves or interstices of the plate, is not readily

Fig. 7.—Winkler.

washed away as is the material of a pasted plate; and (2) that as the peroxide becomes very gradually disintegrated through use its place is continually filled by the fresh peroxide slowly "formed" by the working of the cell upon the surface of the main grid. The pure Planté plate made by casting a grid with very fine channels extending from one side to the other (Fig. 10), is the standard on the continent of

rugations being put on by a pair of toothed rolls.

The Planté plates consisting entirely of soft lead, are made by several different processes; by sawing the slots on both sides; by working into the surface a number of steel disks which cut into and squeeze out the metal between them, but do not remove any; by working over the surface with a sharp tool which takes a series of cuts, each time turning up a shaving at right angles to the surface but not detaching it; by rolling the lead between suitable corrugated rolls; and lastly by casting. The casting process is by far the best of all these, since it is the only one by which the plate can be made with stiffening ribs around the edges or wherever else desired. The product of all these processes is a flat plate from one quarter to a half inch in thickness, composed of a number of thin leaves lying in planes at right angles to the plane of the plate and spaced between 15 and 35 per inch, exposing to the acid a surface from five to ten times that of a plain plate of the same outside dimensions.

As the positive plates made after Planté's method came into increasing demand, manufacturers found that the process of forma-

Fig. 8.—Chloride.

Fig. 9.—Box.

Europe, it having but the one fault, liability to become bent or "buckled" with use, to the extreme detriment of the battery.

In America, however, the type known as the "Manchester" positive has been the most successful. This plate with its prototypes is here illustrated (Figs. 11 to 14), and its distinctive feature is the combination of a stiff alloy grid with pure lead spirals or buttons, which furnish the active material. Since the peroxide of lead is "formed" by an electro-chemical process from the pure lead buttons, this plate is distinctly of the Planté type, but having the great advantage that it is very stiff and practically free from buckling, and its consequent evils, which are so common with the soft lead type. The grid for the Manchester plate is a casting of lead-antimony alloy, having a number of holes three quarters of an inch in diameter, placed as close together as possible and extending all the way through. Into each hole is forced a "button" of pure lead which offers a large surface to the acid; each lead button is made by coiling up a piece of transversely corrugated lead strip or ribbon, made by forcing solid lead under pressure through a suitable slot or die; the cor-

tion was exceedingly slow and expensive and hence they set to work to try to cheapen it. To this end they subjected the plates to be formed to the action of some chemical which would easily attack the surface and leave there a porous layer of a lead salt which could readily be "formed" into peroxide by the oxidizing agency of an electric current. Swan thus exposed his plates to the action of acetic and carbonic acid fumes, and thus covered his surfaces with white lead, while Dujardin dipped his plates into nitric acid and thus formed a layer of lead nitrate; the plates covered with a layer by either of these processes were set up in dilute sulphuric acid and there subjected to the action of a current which converted the porous layer into peroxide. It was soon discovered after this, that these two operations could be carried out together, and that it was thus possible, by adding a suitable amount of nitric acid to the sulphuric acid electrolyte, to form lead nitrate on the surface of the plate and simultaneously by the passage of a continuous current to oxidize the nitrate to lead peroxide. It is now known that the addition of almost any solvent of lead to a sulphuric acid electrolyte will very

ELECTRIC STORAGE BATTERY.

For explanation of figures, see article.

ELECTRIC STORAGE BATTERY

greatly facilitate the forming of plates therein, so that the process which took Planté several months is now done in as many days, nitric acid being the solvent most commonly used.

It has been stated above that the Faure, or pasted type of positive plate, is now used only for automobile work, where lightness is a primary factor, and as illustration of a plate of this kind, the so-called "exide" may be cited (Fig. 15). The grid, as will be seen, consists of a number of small lead alloy bars running parallel, and placed at the two surfaces of the plate in such manner that a bar on one side comes opposite to a blank space on the other. The active material inside the bars is held in so tightly that it can work out only as it disintegrates into very fine particles, as is normally incident to its use; and moreover, the wash of the electrolyte in the cell is much lessened by the lead bars on the surface of the plate.

The life of any plate of this kind is not so long as that of the Planté plate, but its capacity for the same weight is considerably higher, so that for the class of work mentioned it fills a very important place.

In the early days of storage batteries both Planté and Faure used positive and negative plates of identical construction, and any form of positive described above may be used as a negative; but the conditions under which the two plates operate are so different that it is now almost universal to use a special design for each. The main difference is that the metallic sponge lead constituting the negative active

tween them, and the whole group was immersed in the sulphuric acid electrolyte contained in a suitable glass vessel. But this form of cell was soon found very difficult to operate, since the felt gave no security against the plates becoming short-circuited, and it was frequently necessary to remove the whole element from the jar, unroll it, and substitute fresh felt, a matter of great inconvenience. To obviate this defect it has ever since been the practice to use plain flat plates anywhere between one eighth and one half inch in thickness, which either hang from the top or rest on the bottom of the jar, with a small space—one eighth to a half inch—between their adjacent surfaces. The plates are maintained in their proper position by the "separators"; either a pair of glass tubes or hard-rubber strips between each pair of plates, or else a thin sheet of insulating material such as perforated hard rubber. Formerly the glass tubes were most frequently used in large cells, and the perforated rubber sheets in small ones, but a recent development is the use of thin wooden diaphragms between the plates, which possess the great advantage that the particles of lead peroxide which are always present in the electrolyte, can never deposit between the plates

FIG. 10.—Tudor Positive.

FIG. 11.—De Kabath.

material is quite a tenacious substance compared to lead peroxide, and consequently it does not yield to the wash of the electrolyte, and only in cases of the most flagrant abuse does it ever become softened so as to drop off from the grid. Under these circumstances, many of the grids (Figs. 1 to 9) which are quite inadequate to retain the lead peroxide of a positive plate are quite capable of making good negatives, and are in fact so used. The two forms of exide grid (Figs. 15 and 16) are among the best for small light batteries, while the box grid (Fig. 9) is the most largely used for central station work. This plate is made in two halves riveted together and completely surrounding the active material, the acid having access by means of a large number of small holes through the sheet which covers the sides. Under ordinary circumstances it is impossible for the sponge lead to work out of these perforations, so that the life of this type is much greater than that of any other heretofore developed.

Both Planté and Faure in their earlier experiments assembled their batteries by rolling up together in the form of a wide spiral the two sheets of lead which were to serve as positive and negative plates. The two sheets were insulated by means of pieces of felt rolled be-

so as to bridge across and short-circuit them, as often happens with the older types.

The alternate plates in a cell are electrically connected together, the two sets thus resulting constituting the two poles, and considerable care is necessary in order that all the connections may be permanent; the only satisfactory way is to use lead throughout, and to melt or "burn" together the joints with an oxyhydrogen flame. There is then nothing that the acid can corrode and no cracks into which it can work its way so as to spoil a contact. The vessels used for retaining the electrolyte are principally of four kinds, according to the use they are to be put to; hard rubber jars for vehicle and other portable batteries; glass jars for small stationary plants; hard sheet-lead tanks, or lead-lined wooden boxes for medium and large station plants. The plates in the rubber jars rest upon ribs at the bottom; those in glass rest upon the edges of the jars; while in the large alloy and lead-lined tanks they rest or hang by suitable hooks or "lugs" upon glass plates which fit into the end of the cell and stand upon the bottom. (See Figs. 17, 18, 19 and 20.)

Thus far the theoretical side of the storage battery has not been considered, it will therefore be briefly discussed here.

ELECTRIC STORAGE BATTERY

As has been already mentioned, when a battery is fully charged the active material on the positive plates consists of lead peroxide PbO_2 , while that on the negative is porous metallic lead. Knowing that a current passing through weak sulphuric acid liberates oxygen at the pole where it enters the liquid and hydrogen where it leaves, the early investigators supposed that on discharge the oxygen generated at the negative by the discharging current combined with the metallic lead there to produce lead monoxide, while the hydrogen generated at the positive combined with the lead peroxide to form monoxide and water. On charging the cell the reverse process was supposed to occur; namely,

FIG. 12.—C. Smith.

the lead monoxide on the positive plate became converted by the oxygen there liberated into peroxide, while that at the negative was reduced by the hydrogen liberated to the state of metallic lead.

But later investigators, notably Gladstone and Tribe, noticed that the density of the sulphuric acid electrolyte always changed when a cell was either charged or discharged, rising on the former and dropping in the latter case. The amount of this change in density which they noticed was much greater than could be accounted for by the old theory, and hence they were led to examine into the chemical composition of the active material at various stages of charge and discharge. Doing this they found that both plates on discharge instead of being converted into lead monoxide were changed to lead sulphate, and hence the drop in density of the acid. Putting these reactions into the form of a chemical equation, we have:

That this reaction represents approximately the changes taking place in the storage cell is now generally acknowledged, but one thing which the equation does not account for is the fact that it is never possible to obtain anything like the full theoretical capacity from a cell. That is, experience has shown that after one half—at the utmost—of the active material has been turned to sulphate, the e.m.f. of the cell has dropped to zero and we can get no further current from it. The exact reason for this is not easy to give with certainty, but it is generally supposed that as lead sulphate is a very poor conductor it is necessary that a con-

siderable amount of lead peroxide and metallic lead respectively be left in the two plates in order that the active material as a whole shall be a conductor.

If the thermo-chemical equivalents of the above equation be considered it is found that a thermal change of 85,700 to 87,700 heat units is involved; and the temperature coefficient of a storage cell is .022 per cent per degree Fahrenheit. The well known equation of Helmholtz,

$$E = \frac{U}{23073} + T \frac{de}{dt}$$

(where E is the voltage of the cell, U the heat energy of the chemical reactions involved, T the

absolute temperature, and $\frac{de}{dt}$ the temperature

coefficient), gives from these values 1.96-2.01 volt as the e.m.f. of a storage cell at 63° Fahrenheit; while the observed e.m.f. is 1.99-2.01, an agreement which greatly strengthens the theory. Applying to storage batteries the osmotic theory of Nernst, the German investigators Liebenow and Dolezalek conclude that the energy of the discharge is derived from the tendency of the ions of lead peroxide and of metallic lead to go into solution, and surprising as it seems at first sight this view appears to be gaining ground. At various times a great deal of most interesting work has been done upon the theory of storage batteries, yet it must be admitted that the theoretical development is far behind the practical up to the present time, and it is safe to say that, as in the case of most useful inventions, if the pioneers in the art had waited for a full theoretical knowledge the invention would never have been made.

Properties.—The fundamental property of a storage cell is its capability of storing energy, as the name implies. As has been pointed out, the source of the current of the battery is chiefly chemical energy. On the discharge of the cell this is converted directly into electrical energy, whereas on the charge the original chemical constituents are reproduced, with a consequent absorption of energy. The useful energy given out by the cell during discharge is of course never quite equal to that put in during the charge; both the quantity of electricity and its P.D. (that is, the difference of potential between the terminals of the cell) being smaller than in the former case. When a cell is discharging at constant current, its P.D. continually falls off until it reaches zero, the drop being very much more rapid as the end approaches. These phenomena are very much more easily understood by reference to the accompanying illustration (Fig. 21), in which the abscissæ represent time in hours and the ordinates show the P.D. between the terminals. The cell has not been completely discharged until the P.D. reaches zero, but since the latter end of the discharge would be of very little value, and beside this it is found very injurious to the cell to completely exhaust it, the usual practice is to stop the discharge when the voltage reaches some definite value, usually 1.8 for the normal rate, 1.7 for the hour rate, and the "capacity" is the number of ampere hours given out to this point. Similarly, when a cell is charged with constant current the P.D. gradually rises as illustrated in

ELECTRIC STORAGE BATTERY

the upper curve (Fig. 21), but here it will be noticed that there is quite a definite point when the charge is completed, namely when the P.D. reaches a maximum value, as at the point

the temperature, and at constant temperature inversely with the rate of discharge. Within the ordinary range of working temperatures the capacity varies very nearly 1 per cent for every two degrees above or below 70° Fahrenheit.

Inasmuch as the energy of the cell is derived from the chemical substances which compose it, it would seem that the energy obtainable at a given temperature would be quite independent of the rate of discharge; such, however, is not the case, for when a high discharge rate is used the active material at the surface of the plate becomes quickly sulphated and forms a partial shield which prevents the acid from acting upon the material throughout the mass of the plate. On this account all types of lead storage battery give considerably less capacity at high rates of discharge than at low, but the amount of variation depends largely upon the construction of the cell.

Secondly, from the chemical equation of the discharge of the battery it follows that the amount of sulphuric acid available puts a limitation upon the capacity of the plates, and hence if the amount of acid in the cell be very small, so that at even high rates it is all used up, the capacity can be no higher at a low rate. This condition is never fully realized in practice, but in small cells for automobile use, where everything is cut down to the lowest weight, the amount of acid is very small and the capacity consequently varies but little with rate. In the case of a cell with a large excess

marked "B"; this point "B" shows that the plates have absorbed as much oxygen and hydrogen as they can hold, and if the cell be examined at this time these gases are found to be liberated in large quantities, causing a boiling or "gassing" that is very characteristic of the charged cell.

The capacity of the cell, that is the number of ampere hours it can give out on discharge is generally the measure of its useful size, and is the chief property by which it is bought and sold. A consideration of some of the most important points bearing on capacity is therefore of the highest importance. Firstly, the capacity of an individual cell is by no means constant, as might at first thought be assumed. The capacity at any given rate of discharge varies directly as

of acid the capacity varies nearly inversely as the square root of the rate of discharge, whereas in the case of automobile batteries it is much more nearly constant, being sometimes as low as the fifth root of the current; both these rules holding only within the ordinary range of currents. The variation of capacity with the rate is also somewhat dependent upon the type of plate used, since with very thin or very porous plates the acid is able to attack all parts of the active material more readily than with a thick or very compact one; but the effect of different kinds of plates upon this phenomenon is not so marked as might be expected.

In stating the capacity of a battery it is thus necessary to specify the rate at which it is to discharge, and the rate ordinarily assumed is

ELECTRIC STORAGE BATTERY

that which a battery of stationary type can maintain for eight hours ; or for three or four hours if of the vehicle type.

In the lightest types of vehicle batteries it is found possible to obtain about 15 ampere hours per pound of active material, or 26 per cent of the theoretical capacity, but when the lead grids, acid, jar, connecting straps, and other accessories are included beside the active material, it is found that practically the best attainable for commercial conditions is five to six ampere hours per pound total weight of cell ; while in the large station types about one third this figure is attained.

A few words with particular regard to the electrolyte may be in place here. The two main functions of the electrolyte are first as a conductor of the current from one plate to the other, and secondly to furnish sulphuric acid, which shall enter into combination with the active material of the two plates on discharge. So far as the first function is concerned it would be preferable to use sulphuric acid solution of about 1.25 specific gravity, since that density gives the greatest conductivity. So far as regards the second function, the greater the density of the acid the better, since this would mean that a smaller total weight of electrolyte would furnish the necessary amount of acid for the discharge of the plates. But, unfortunately, there is a third consideration which must be given due weight, and that is the physical effect of the acid upon the plates. It is found that as acid above 1.2 specific gravity is used it begins to have an injurious effect upon the plates, whereas if under 1.15 it fails to carry out properly the second function, and in consequence the full capacity of the plates is not available. For ordinary usage, therefore, the electrolyte is used which shall be about 1.2 specific gravity in the charged condition of the cell, and in such amount that on discharge of the cell it will drop to about 1.15. In the automobile cells, however, it is usual to use acid that is somewhat heavier than this—as high as 1.250° to 1.300°—in order that a smaller amount of it may suffice to furnish the necessary lead sulphate on discharge ; the slightly less endurance of the plates being more than made up for the smaller total weight of the cell.

The mean P.D. of a battery on discharge may be taken at 1.9 volts, so that the maximum energy capacity is—for the vehicle type—about 10 to 12 watt hours per pound ; or, in other words, if all the energy of the cell could be expended in lifting the latter it would raise it 26,600 to 31,900 feet high. The magnitude of this figure is perhaps better realized by noting that it is about 100 times as great as the amount of energy which can be stored in a pound of elastic rubber, and 1,700 times as great as the amount that can be stored in a pound of steel wire having an elastic limit of 60,000 pounds per square inch.

The next important property of a battery is commonly its efficiency, and this is one of the determination of which requires considerable care. Two curves of charge and discharge (Fig. 21) are sufficient to give the efficiency, but a chance for error lies in the fact that it is difficult to tell whether both of these curves will represent the performance of the battery for a continued period. It is found always necessary to charge for a greater number of ampere hours

than are taken out on discharge, and the only way to tell how much this "overcharge" must be is to run a battery continuously for some time and carefully measure each charge and discharge. By carrying this out it is found that from 5 to 10 per cent more must be put in, in order to keep the battery in a properly charged condition, than is taken out. Furthermore, as these same curves illustrate, the mean voltage on charge is considerably higher than on discharge, and here is another source of loss. Taking the battery working at its eight hour or normal rate, the mean charge voltage will approximate 2.21, the mean discharge 1.91 ; summarizing, then, the voltage efficiency is 86½ per cent, the ampere hour efficiency is 92½ per cent, and the watt hour efficiency 80 per cent.

This last figure, the energy efficiency, is that which may be commonly obtained from a battery continually worked to its full normal rate capacity. A battery on the other hand, performing "regulating" work, that is, the steadying of a load which is subject to very large fluctuations of short duration, is called upon to alternately discharge and charge at rates as high as four to eight times the normal, lasting, however, for fractions of a minute only. Working at this service it is usual to give an overcharge once in several days, or once a week, and in the interval the battery is working at an ampere hour efficiency of almost unity, since the plates, being always only partly charged can always take up all of the charging current without the development of any gas. The periodic overcharge reduces the mean efficiency somewhat, so that 94 to 96 per cent is usually obtained in this kind of service. The voltage efficiency in this case is not materially different from that already considered, for while on the one hand the loss due to internal resistance is higher, on the other hand the successive cycles of charge and discharge follow each other so closely that the P.D. has not time to reach its ultimate value before the current is reversed and another value sought. The mean voltage which a battery maintains under these conditions, commonly called its "floating point," lies between 2.05 and 2.1 per cell ; and the shorter the intervals of charge and discharge and the lower the current the less is the departure from this mean value, while long intervals and higher currents cause the voltage to fall more on discharge and rise more on charge. With intervals such as commonly occur of from a quarter of a minute to a minute duration, and with current rates of four times the normal, the variation may be taken as 5 to 8 per cent on both sides of the floating point, and the watt hour (or energy) efficiency will then approximate 90 per cent.

To summarize the whole question, the efficiency of a storage battery in practical operation is usually between 75 and 90 per cent, the former figure applying where current rates are high and the battery plates large, and where full capacity is used, the latter where, though the current may be high, the duration of each discharge is very brief ; and the efficiency attainable in any given case is also somewhat dependent upon the temperature, type, and general condition of the battery.

The resistance is frequently an important consideration in the operation of a large battery plant, and it is the remarkably low value of this quantity which makes it possible to draw from

ELECTRIC STORM — ELECTRIC TORPEDO

a storage cell a very much heavier current than from a primary cell of similar dimensions. Depending upon the size and type of plates, the separation, and the condition of a cell as to whether charged or discharged, the resistance varies between .03 and .08 ohms, divided by the normal or eight hour rate of the battery in amperes, the lower value holding nearly constant throughout most of the discharge followed by a rapid rise near the end. The resistance here referred to may be called the virtual resistance, being obtained from two readings of the cell voltage, first with current flowing and second on open circuit, and the difference between these two readings, termed the "drop," divided by the current, gives the virtual resistance. This virtual resistance is composed of two main factors, the resistance proper of the electrolyte, the plates, connections, etc., and a certain polarization resistance at the surface of the plates, and the accurate measurement of each of these factors separately is a matter of so much difficulty that it is seldom attempted.

Storage Batteries Other Than Lead.—Thus far there has been considered but one genus of storage battery; namely, that using lead or lead compounds as the active material, and dilute sulphuric acid as the electrolyte. To the present time no storage cell using other constituents than these has come into any extensive use, but there are three other classes which deserve to be noticed. The first class, the zinc-lead cell, may be regarded as a cross between the ordinary primary cell and the lead storage cell, since in the matter of a negative it follows the former class, and in the matter of a positive the latter, while the electrolyte is sulphuric acid, used sometimes with the primary, always with the lead storage battery. Upon discharge the zinc constituting the negative is dissolved to form zinc sulphate, while the lead peroxide on the positive is reduced and converted into sulphate. Since it is always troublesome to continually dissolve and re-deposit the material of a plate without destroying its original shape, a plan frequently adopted in this class of battery is to deposit the zinc upon a thin pool of mercury in the bottom of the jar, which keeps it always fully amalgamated and tends to prevent its dissolving by local action. This expedient, however, necessitates an awkward construction of cell, with very high resistance, and it is found in practice to have a very low efficiency beside, though it has the advantage of giving a very high P.D. of between 2 and 2.25 volts. This class of cell is applicable only where low currents are used and where weight is not a great factor.

The second class of storage battery, other than lead, is known as the copper-zinc, and its chief distinction from those heretofore considered is the use of an aqueous solution of caustic potash as electrolyte. The negative, as in the last class, consists of metallic zinc which dissolves on discharge, but the positive is composed of cuprous oxide, which on discharge simply becomes reduced to the metallic state. This class possesses the disadvantage of the first class, that it is very troublesome to dissolve and re-deposit the zinc continually without its becoming very lumpy and uneven, and moreover the cupric oxide which may be formed on overcharge is slightly soluble and may thus cause a great deal of trouble. A further drawback incident to

this class is its exceedingly low P.D. of only .8 volt.

The third class holds much the same relation to the copper-zinc as the lead cell holds to the lead-zinc, for it uses caustic potash solution as electrolyte, but replaces the soluble zinc negative by a grid pasted with an insoluble metallic sponge. Upon discharge, the metallic sponge becomes oxidized, while the metallic oxide on the positive becomes reduced, and on charge the original condition is reproduced. A great many experiments have been made, notably by Edison in this country and Jungner in Sweden, to determine the best active materials to use in this class of battery, but so far apparently without any very definite result. For the negative, iron and cadmium have been somewhat successful, while for the positive, nickel, cobalt, copper and silver have been recommended. The chemical reactions taking place in a cell of this class are approximately represented as follows:

Charged Cell. $\text{Fe KOH H}_2\text{O Ni}_2\text{O}_3 = \text{FeO KOH H}_2\text{O Ni}_2\text{O}_3$

Discharged Cell.
It will be noticed that this reaction is very simple and direct as compared with the reactions of any of the other classes of storage batteries, since the electrolyte maintains its composition unchanged and acts simply as a means of transporting oxygen from one plate to the other. The energy of the discharge is derived solely from the greater affinity of iron than nickel for oxygen, and consequently this class is often called the "oxygen lift" battery. The advantages claimed for this class of battery are greater capacity per unit weight, and longer life, against which must be counted the low P.D. of only 1 to 1.25 volts; and up to the present time the claims have not been commercially demonstrated, so the ultimate success of the class yet remains to be determined.

The lead storage cell on the other hand, in spite of some inherent faults, possesses such well established valuable qualities that it is constantly proving itself a commercial necessity, and is now recognized both in this country and in Europe as a standard piece of electrical equipment, in just the same light as are boilers, engines, and dynamos. See BATTERY; DYNAMO; ELECTRICITY.

Electric Torpedo, a torpedo operated by electricity. There are various kinds of electric torpedoes. The Sims-Edison torpedo is driven by an electric motor, and its motions are controlled from the shore by electricity. The torpedo proper is carried some distance below the surface of the water by a vessel immediately

ELECTRIC TRANSMISSION—ELECTRIC VEGETABLE GARDENING

above it, from which it is suspended by two rigid bars. In the torpedo is a cable reel on which the conducting cable is disposed. An electric motor and controlling gear are also contained within the torpedo. In its front the explosive is placed. It is driven by a screw propeller actuated by the electric motor. As it moves it pays out cable so that it has no cable to draw after it through the water, the cable lying stationary in the water behind it. This avoids frictional resistance to its motion. The maintenance of the torpedo at a proper depth is one of the advantages of the system over other methods.

Electric Transmission of Energy, the transmission of motive power by means of an electric current. Recently there has been a tendency on the part of electrical engineers to turn their attention to the problem of utilizing heads of water for the purpose of generating electric energy to be used in furnishing light and power, not only to the towns near which they are situated, but by electric transmission to towns at a distance. At the beginning of 1903 there were 485 of these electric power plants in the United States, the most important of them being that of the Niagara Falls Power Company, at Niagara Falls, N. Y., which on 17 Nov. 1896, sent 1,000 horsepower of electric energy from Niagara Falls to Buffalo, N. Y., a distance of 26 miles, where it was successfully utilized in propelling the street cars of the Buffalo Railway Company. This transmission scheme is still in successful operation; its capacity is being gradually increased, and will continue to be until it is capable of transmitting 20,000 horsepower of electric energy. During the electrical exhibition held in New York in May 1896, about one thirtieth of a horsepower was transmitted from Niagara Falls to the exposition building, a distance of 453 miles, where it was successfully used to operate a working model of the Niagara Falls Power Company's plant. This is the longest electric transmission of energy ever attempted.

Electric Vapor Lamp, a recent invention known as the Cooper-Hewitt mercury vapor lamp; said to be the most original and important discovery in relation to general distribution of electric current for light and power purposes that has been brought to public attention since the advent of the commercial use of electricity. This remarkable device, in the shape of a small globe less than one foot in diameter, converts alternating to direct current, and the claim is made that by reason of its simplicity, cheapness, great efficiency and absence of moving parts, will eventually displace the large and costly apparatus now used everywhere. See VAPOR LAMP, THE HEWITT MERCURY.

Electric Vegetable Gardening. Experiments carried on at the government agricultural station at Amherst, Mass., since 1900, show that the use of electricity by the farmer is a distinct and valuable stimulus to nature and exerts a marked influence upon the germination of seeds and the growth of farm products. Scientists argue that roaming around loose in the atmosphere there is a vast fund of electrical force, which by means of specially devised apparatus, can be attracted to the earth and distributed through the ground where the gardener has sown his seeds. The apparatus by means of

which the electricity is caught and harnessed has been tested at Amherst and has proved to be a complete success. Briefly described it consists of a number of copper spikes which are elevated at the top of a 50-foot metallic pole. These spikes gather the electric fluid from the atmosphere and convey it to the foot of the pole, where it is caught by wires buried a few feet beneath the ground and distributed over as large a section as the gardener desires. Each of the poles will gather and distribute enough electricity to cover several acres of ground. With this apparatus experiments have been made which may be summarized as follows: After seeds have been subjected to the electric treatment for a period of 24 hours, it was found that over 30 per cent more seeds were germinated by the aid of electricity than in a like quantity of seeds sown in ground that lacked the electrical stimulant. As the scientists in charge of the experiments wished to make a very complete test, the electric current was applied to seeds that were allowed to stay in the ground for 48 hours. In this case it was found that 20 per cent more seeds had germinated in the electrified ground than in the soil where the seeds had been left to sprout under normal conditions, and in 72 hours this percentage had dropped to 6, thus showing that the use of the current for the purpose of stimulating germination under all the tests was a decided success.

In the various tests seeds subjected to only a temporary current of electricity have been found to show the effect for a few hours and then resume their normal growth. In one instance to produce a constantly beneficial effect it was necessary to apply the electricity every hour to germinate growing plants or seeds. In order to obtain a specific illustration of the effect of electricity, 100 seeds of the horse-bean were sown in moist sawdust, 24 of the seeds having been previously selected as seeming to nearest resemble each other. On the radicle of each of these was placed a dot of indelible ink one centimetre from the tip. The beans were sown and received hourly stimulation, lasting about 30 seconds, for a period of 48 hours. The growing plants were carefully measured, the dot of ink being the constant point from which their increase could be determined. It was found at the end of 12 hours that the gain per cent by the use of the electric current was 19.11; at the end of 24 hours the gain per cent was 44.95; at the end of 36 hours the gain was 42.13 and at the end of 48 hours 39.47. Repeated experiments on the same line produced almost precisely the same results.

Another interesting experiment made in 1902, was planting in two sections of ground, the soil in both of which had been carefully selected to ensure it being exactly alike, seeds of the following varieties: parsnip, lettuce, carrot, turnip, radish, and onion. To one of the sections of ground a mild current of electricity was applied. The following day the plants in the electrified plot began to appear, the turnips sprouting first. The rapidity of growth of those planted in the electrically treated ground was far in advance of those treated in the ordinary ground. The second day plants broke through the surface in both plots, those in the electric garden showing considerably the more rapid growth; the foliage was rank, and when harvested was nearly twice as high as that of the non-electric plot. The

ELECTRIC VOLTAIC BATTERIES—ELECTRO-CHEMICAL INDUSTRIES

roots also were larger and showed a marked difference in favor of electricity. One peculiarity was that in the electric plot for every pound of roots very nearly a pound of tops was produced, while in the other case for every pound of tops there grew 1.43 pounds of root, but the difference in the total was all in favor of electricity. With reference to the other vegetables, the lettuce proved a failure in both plots. The carrots showed a marked superiority in the electric bed over those in the non-electric. The onion plants came up in both beds and grew finely for a time, then blasted and not one developed, neither electric nor non-electric, this being the only case of all the vegetables where no tangible results were obtained. Next to the parsnips, the radishes gave the best results. They grew rapidly, those in the electric garden being always ahead. The tops were rank and the roots were crisp. When the best of the radishes in each plot were pulled, washed and weighed, it was found that the six largest roots taken from the electric plot weighed two ounces more than the six largest ones taken from the non-electric plot. They were larger individually, the tap root was longer, were of a finer flavor, of better quality, more brittle, and every way superior to those raised without the aid of electricity. The two largest radishes taken from the electric row weighed 14 ounces, while the two largest from the non-electric row weighed 10 ounces, or 4 ounces in favor of electricity.

Besides the electric treatment of the soil, experiments have been made with the electric light for stimulating the growth of plants, and the general effect has been to hasten the maturity of lettuce, spinach, and similar products. It has been found that the electric light has the stimulating effect of daylight upon the plants, and crops thus encouraged by light from arc lamps have showed 50 to 60 per cent increase. In short it has been clearly demonstrated that by means of electricity nature can be forced to do double duty without lessening the worth of her products.

Electric Voltaic Batteries. See BATTERY; ELECTRICITY; PRIMARY BATTERIES.

Electric Waves. See ELECTRICITY.

Electric Welding, the process of uniting together two pieces of metal, the necessary high temperature at the junction being obtained by the passage of a powerful electric current across it. The pieces of metal are placed end to end and subjected to some pressure. A very strong current is then sent along them, and as there is imperfect contact, and consequently a high resistance, at the junction, intense heat is developed there. The metals soon unite perfectly, and the junction is hammered into shape. In all cases the junctions must be perfectly clean, and different fluxes, depending on the nature of the metals, are used to prevent oxidation during the heating process. In the case of iron, borax is the flux usually employed. Since the currents employed for the purposes of welding are necessarily exceedingly powerful, it is found more economical to use for the purpose alternating currents which are passed through a transformer and emitted at a reduced pressure and an increased strength.

Electrine, (1) The principle of electricity; a kind of matter which manifests electrical phenomena. (2) Made of amber or electrum.

Electrizer, an apparatus for the application of electricity for medical purposes. See ELECTROTHERAPEUTICS.

Electro-ballistic, pertaining to projectiles and to electricity. An electro-ballistic apparatus is an instrument for determining by electricity the velocity of a projectile at any part of its flight. The projectile passes through a wire screen, thus breaking a current of electricity and setting in motion a pendulum which is arrested on the passage of the projectile through a second screen. The distance between the screens being known, the arc through which the pendulum vibrates measures the time due to the flight of the projectile between the screens. See GUNNERY.

Electro-ballistic Machines. See GUNNERY.

Electro-biology, the science which treats of the electric currents developed in living organisms; also the department of knowledge which treats of the influence or control over the feelings, thoughts, and actions of a mesmerized person.

Electro-bronze. See ELECTROPLATING.

Electro-chemical Industries. The word electro-chemical is here used to include electro-metallurgy, as there is no generic term for the two subjects. Electro-chemistry may be defined as that branch of science relating to the electrical production of chemical substances and chemical action, or to the generation of electrical energy by chemical action. On the other hand electro-metallurgy is the branch of science that relates to the electrical production and treatment of metals.

Electrolytic Refining of Copper.—The largest and most important of all electro-chemical industries is the refining of copper, which is conducted at many places in this country and abroad. The process of refining copper electrolytically consists in the transfer of copper from the anode to the cathode, by the selective action of the electric current, and in leaving the impurities behind in the anode, electrolyte, and in the slime or sediment.

The material at present subjected to profitable electrolytic refining is crude copper containing from 96 to 98 per cent pure copper, and varying amounts of silver, gold, nickel, iron, arsenic, antimony, sulphur, etc. This crude copper is obtained from various copper ores by smelting, and is cast in iron molds into anode plates, which are about 3 feet long, 2 feet wide, and 1 inch thick, weighing approximately 250 pounds. The cathode plates are of electrolytically refined copper, practically the same in length and width as the anodes but only 1-20 inch thick. The electrolyte, or bath, in which the plates are suspended is a solution of 12 to 20 per cent copper sulphate, and 4 to 10 per cent sulphuric acid, the latter being introduced to decrease the resistance of the bath which is kept at a temperature of about 40° C. The containing tanks are of wood, usually lined with sheet lead or carefully coated with a pitch compound, and of such dimensions that a distance of about 1 inch exists between the faces of the plates. In some

ELECTRO-CHEMICAL INDUSTRIES

cases the plates are arranged in series, and in others in parallel or multiple, as illustrated. The former has the advantage of requiring electrical connections to be made at the first and last plates only, whereas the parallel system requires a connection at every plate; but in the series system the leakage of current due to the short-circuiting action of the sediment and sides of the tank is from 10 to 20 per cent, so that the parallel is more generally used. The connections between the various plates to the circuit in the parallel systems are made by copper rods, which are run at two different levels along the edges of the tanks, one bar for each set of plates. In some instances these rods are of the inverted V shape, so that the edges will cut through any corrosion which may happen to form at the points of contact. The vats are arranged with respect to each other, so that each is accessible from all sides, and the circulation of the electrolyte is possible. This circulation may be obtained by blowing a stream of air through the electrolyte, but more frequently by arranging the vats in steps, and piping so that the electrolyte may pass from the top of one vat to the bottom of the next, as shown in the illustration. This maintains a uniform density of electrolyte which is necessary for the proper formation of the deposit. The electrical pressure required is from .2 to .4 volts per tank, with a current density of 10 to 15 amperes per square foot of cathode plate surface. The individual vats are connected in series, so that the total voltage required may be approximately the same as that which the generator furnishes, being usually 110 volts. In practice from 400 to 500 ampere-hours are required per pound of copper deposited, the theoretical amount according to Faraday's law being only 386.2 ampere-hours. The loss varies from 4 to 20 per cent according to the system employed.

The cost of refining copper by the electrolytic method is from $\frac{1}{4}$ to $\frac{3}{4}$ cent per pound. The following products of refining are marketed: Commercial cathodes, which are sometimes shipped to consumers, but more frequently cast into wire bars, ingots, cakes, or slabs of standard dimensions and weight. They usually assay from 99.86 to 99.94 per cent pure copper. The yield in commercial cathodes is from 97 to 99 per cent of the anodes treated, excluding the anode scrap which varies in weight from 7 to 15 per cent of the original anode in parallel plants, but this scrap is not a loss as it is collected and recast into anode plates. Besides electrolytic copper, most plants secure gold, silver, and nickel salts in the slime, from which the metals are recovered. The electrolytic refineries in the world are now producing copper at the rate of 322,295 tons annually, valued at \$96,688,500, with copper selling at \$300 per ton, in addition the by-product in recovered gold and silver is valued at \$20,000,000 per annum. There are now in active operation 33 electrolytic refineries, with a total generator capacity of 20,000 kilowatts, 10 of these are in the United States, and supply about 86 per cent of the world's product; 6 plants are in England and Wales, producing about 9 per cent; while the remaining plants are on the continent of Europe.

Aluminum.—Practically the output of this metal for the entire world is now produced electrolytically. The only process used on a large scale is that invented independently in

1886 by Charles M. Hall in the United States and by Paul L. V. Héroult in France. This process consists in electrolyzing alumina dissolved in a fused bath of cryolite. The alumina is obtained from the mineral bauxite which occurs abundantly in Georgia, Alabama, and other regions. The natural material, being a hydrated alumina containing silicon, iron and titanium, must be treated in order to drive off the water and eliminate the impurities. Formerly this was accomplished by a chemical process, but now it is effected more simply and cheaply by heating the material mixed with a little carbon in an electric furnace. The impurities are thus reduced and collect as a metallic regulus in the bottom of the mass. This leaves the alumina nearly pure and it may be tapped off while fused or easily separated by breaking it up after cooling. In practice it requires two pounds of alumina for each pound of aluminum produced. The flux or bath in which the alumina is dissolved consists of cryolite, a natural double fluoride of aluminum and sodium ($\text{Al}_2\text{F}_6\text{NaF}$) found in Greenland. This is melted in a large carbon-lined, sheet-iron tank which constitutes the negative electrode, a group of suspended carbon rods forming the positive electrode. A current of several thousand amperes at 6 to 7 volts is used. Only a portion of this voltage is required to decompose the alumina, the balance amounting to about 4 or 5 volts represents the heat produced which keeps the bath melted. The passage of the current causes the aluminum to deposit on the bottom of the tank as a fused metal, being drawn off periodically. The oxygen set free combines with the carbon of the positive electrodes and passes off as carbonic oxide. The reaction is $\text{Al}_2\text{O}_3 + 3 \text{C} = 2\text{Al} + 3 \text{C O}$. About one pound of carbon is consumed for one pound of aluminum produced. When the alumina becomes exhausted from the bath, the voltage rises and lights a lamp shunted across the electrodes, thus giving notice that more material is needed. Each electrical horsepower produces about one pound of aluminum per day of 24 hours. According to Faraday's law the weight of aluminum deposited by 1,000 amperes is .743 pound per hour. The actual yield of metal by the Hall process is about 85 per cent of this theoretical amount. The total power used by the various works employing the Hall process, is very large and amounts to more than 15,000 horsepower in the United States and Canada. The total power employed in European plants operating under the Héroult patents is nearly as great. The metal when drawn from the tanks is cast into rough ingots which are afterwards remelted and converted into commercial shapes, such as sheets, rods, wires, etc.

Electrolytic Production of Caustic Soda.—

The production of caustic soda (NaOH) and chlorine (Cl) by the electrolysis of common salt (NaCl) is readily realized experimentally ($\text{NaCl} + \text{H}_2\text{O} = \text{NaOH} + \text{Cl} + \text{H}$), but its successful accomplishment on a commercial basis is difficult because of the secondary reactions which take place, forming a mixed product of caustic, salt, and hypochlorite of soda. These difficulties are avoided by separating the caustic soda or sodium that is formed, either by a porous diaphragm, by drawing it off as soon as formed, or by absorbing the sodium deposited in mercury or melted lead.

ELECTRO-CHEMICAL INDUSTRIES

The two most successful systems for the electrolytic production of caustic soda and chlorine from common salt, are the Castner-Kellner and the Acker processes, one operating at moderate temperatures (40°C.) and the other at high temperatures (850°C.). The Castner process employed in this country at Niagara Falls is as follows: The electrolytic tank consists of a slate box, 4 feet long, 4 feet wide, and 6 inches deep, the joints being made by means of a rubber cement. Two slate partitions reaching within 1-16 inch of the bottom (under which are grooves) divide the cell into three compartments, each 15 inches by 4 feet, sealed from each other by a layer of mercury covering the bottom of the tank to a considerable depth. The outside chambers through which the brine is passed are provided with carbon anodes, shaped like a rail section, the broader flange being placed about half an inch above the mercury. These compartments are provided with tight covers and exhaust pipes of rubber and lead, to lead the chlorine away. The central compartment has an iron cathode, of 20 upright strips, and is supplied with pure water, which is drawn off whenever its specific gravity increases to 1.27 due to the presence of the manufactured caustic, while the liberated hydrogen is led from this chamber by means of pipes and used as a fuel for the concentration of the caustic. The tank is pivoted at one end on a knife blade and rests at the other on an eccentric, which raises and lowers that end of the tank about half an inch every minute and causes a circulation of the mercury between the outer and middle compartments. The current passes into the outer chambers, splits up the sodium chloride (common salt, NaCl) into sodium and chlorine (Na and Cl), the latter is liberated at the carbon anodes and passes through the exhaust pipe to the absorption chambers where it combines with slacked lime to form bleaching powder. The sodium combines with the mercury forming sodium amalgam, which by the tilting of the tank passes to the centre chamber, where it serves as the anode, and combines with the water to form caustic soda (NaOH) and hydrogen (H), which appears at the iron cathode. Each of these tanks uses 630 amperes at 4.3 volts. The theoretical voltage required is but 2.3, the remainder being utilized in overcoming the ohmic resistance of the electrolyte and in keeping it warm. The output of this process per horsepower per day is 12 pounds of caustic and 30 pounds of bleaching powder for each cell. The product of this process contains from 97 to 99 per cent caustic, 1 to 2 per cent sodium carbonate, .3 to .8 per cent of sodium chloride, and traces of sodium sulphate and silicate of sodium.

The Acker process, also used at Niagara, to obtain caustic soda and chlorine from salt, is similar to the Castner-Kellner process just described, but differs in that it employs molten lead in place of mercury as a seal, fused salt instead of brine as the electrolyte and operates at a temperature of 850°C. which is required to maintain the fused condition of the electrolyte. The containing tank is a cast iron vessel 5 feet long, 2 feet wide and 1 foot deep, the sides above the molten lead being covered with magnesia so that the current must pass from the carbon anodes to the lead which acts as the cathode. At one end of the tank is a small

compartment separated from the remainder of the vessel by a partition dipping into the lead to such a depth that nothing but this fused lead can pass from one compartment to the other. In the smaller compartment the lead is subjected to a stream of steam, which acting upon the lead sodium alloy forms caustic soda and liberates hydrogen. At various intervals the caustic, which is in a fused state, is drawn off and allowed to solidify, thus avoiding the evaporation of the water which is necessary in the Castner-Kellner process. The current employed per vessel in the Acker process is 2,100 amperes at from 6 to 7 volts, of which energy 54 per cent is used in chemical action, and the remainder in maintaining the temperature.

Potassium Chlorate is produced electrochemically in considerable quantities, both here and abroad. The Gibbs process, used at Niagara Falls, consists in the electrolysis of potassium chloride solution, using a copper or iron cathode and a platinum anode. The current density is high, being 500 amperes per square foot of anode. Each cell uses about 4 volts, of which 1.4 is required to convert chlorid to chlorate, and the remainder produces the heat that maintains the electrolyte at from 50° to 70°C. , which is necessary for the proper reaction.

Electrolytic Chemical Effects, such as bleaching, have been produced through the action of chlorine or other matter set free by an electric current. It is possible in this way to cause substances to act while in the nascent state, and therefore more powerful. Disinfecting and deodorizing of sewage has also been accomplished in a similar manner.

Calcium Carbide.—This compound is produced by the electrothermal process, invented by Willson in 1891, the total output throughout the world being about 300,000 tons in 1902. Its value lies in the fact that 1 pound of this substance mixed with water produces theoretically 5.5, and actually about 5 cubic feet of acetylene, equivalent in illuminating power to about 70 cubic feet of ordinary gas. The reaction producing acetylene is $\text{CaC}_2 + \text{H}_2\text{O} = \text{CaO} + \text{C}_2\text{H}_2$. Various forms of electric furnace have been employed in the production of calcium carbide. One type invented by King and represented in the illustration, consists of an iron car A, which holds the materials and carbide at the same time acting as one electrode. It can be run into place or removed as desired, and being provided with trunnions its contents may be tipped out. The other electrode consists of a bundle of carbon plates carried by a heavy rod C, composed of a copper strip strengthened by iron side bars. The material, which is fed through the channels G F, consists of a mixture of 1 ton of burnt lime and $\frac{3}{4}$ ton of ground coke to produce 1 ton of carbide, the reaction being $\text{CaO} + 3\text{C} = \text{CaC}_2 + \text{CO}$. An arc is first formed between the electrode C and the floor of the truck. The resulting high temperature converts the mixture into carbide, the electrode being gradually raised and more material added until the car is nearly filled with the product, when it is run out and replaced by another. At Niagara Falls a rotary form of furnace invented by C. S. Bradley is used, being operated continuously and producing about 2 tons in 24 hours when supplied with 3,500 amperes at 110 volts, or about 500

horsepower. Since no electrolytic action is required an alternating current is employed.

Barium Compounds.—The principal source of barium is barite or heavy spar, the natural sulphate. Processes for converting this material into barium hydrate, nitrate, chlorid and other soluble salts have been invented by C. S. Bradley and C. B. Jacobs. They consist in melting in an electric furnace a mixture of barium sulphate with a small quantity of carbon. If one part of carbon to 5 parts of sulphate be present, the sulphate would be all reduced to sulphid, but with one fourth as much carbon a corresponding amount of sulphid is produced which reacts upon the unchanged sulphate and the oxid is obtained, the two reactions being as follows:

The carbonic oxide (CO) and sulphurous acid (SO₂) pass off as gases, the latter being used to make sulphuric acid. The fused barium oxide (BaO) is tapped off, cooled, broken up and then digested with hot water. On cooling, barium hydrate [Ba(OH)₂·8H₂O] crystallizes out. This is used in extraction of sugar, making of white paints, "softening" water, and producing other barium compounds.

Cyanides of Potassium and Sodium are produced electro-chemically by the process of C. S. Bradley, C. B. Jacobs and others. A mixture of barium oxide or carbonate is heated in an electric furnace to produce barium carbide (BaC₂). While the mass is still hot, nitrogen gas is passed through it and barium cyanide is formed, the complete reaction being:

The barium cyanide thus produced is treated with sodium carbonate, the result being a mixture of sodium cyanide and barium carbonate. The former is separated by dissolving it in water, the insoluble barium carbonate being used over again. Potassium cyanide is made in a similar manner, and either salt is suitable for gold extraction and other purposes for which cyanides are employed.

Carborundum is a commercial name for carbon silicide, which is produced in large quantities according to the inventions of A. G. Acheson and his assistants. It is used as an abrasive, being hard enough to scratch ruby. It is formed by intensely heating in an electric furnace, a mixture of 3½ tons of ground coke, 6 tons of sand, and about 1½ tons of sawdust and salt, the yield being 3 or 4 tons of crystalline carborundum and about as much more of the amorphous material. The furnaces used at Niagara Falls consist of simple brick hearths 16 feet long and 6½ feet wide, with solid brick walls at each end, about 2 feet thick and 6 or 8 feet high as illustrated. In the middle of each of these walls there are iron frames through which the current is led to a core composed of carbon, weighing about 1,000 pounds, and extending the entire length of the furnace. This core is raised to a very high temperature by passing through it for 36 hours, an alternating current of about 1,000 electrical horsepower at 190 decreasing to 125 volts. The heat from the core permeates the mass and converts it into carbon silicide which is broken up after the furnace has cooled and used to make hones, wheels for grinding, etc.

Artificial Graphite.—As an outgrowth of the carborundum process, Mr. Acheson has developed on a large scale the manufacture of artificial graphite. The material ordinarily used is anthracite coal ground to about the size of rice, which is raised to an exceedingly high temperature in a long electric furnace in the form of a trough about 2 feet square and 30 feet in length. An alternating current of about 1,000 horsepower at 220 to 80 volts is passed for 20 hours longitudinally through the mass, which becomes converted into graphitic carbon. Another line of manufacture consists in graphitizing moulded articles of carbon, such as blocks and rods for electrodes, which are piled in a furnace similar to that described for converting coal into graphite. By using different materials and conditions the two methods produce different kinds of graphite suitable for lubrication, crucibles, pencils, stove polish, electrodes, etc.

Electric Smelting.—One of the earliest commercial processes in electro-chemistry was that devised by E. H. and A. H. Cowles in 1884. A mixture of about 2 parts of alumina, 1 or 2 parts of granulated copper and 1 or 2 parts of carbon was introduced in a brickwork chamber. Bundles of carbon rods inserted at the ends formed the electrodes between which a current of 3,000 amperes at 50 volts was maintained. At a very high temperature the alumina was reduced (Al₂O₃ + 3C = Al₂ + 3CO) and the resulting aluminum combined with the copper to form aluminum bronze.

Iron and Steel can be produced by reducing iron ore with carbon in an electric furnace. For example, a mixture of magnetite and carbon can be heated by passing a current through it as in the Cowles aluminum bronze process, through a carbon core in contact with the material as in the carborundum process, or by the action of an arc as in the carbide process. The reaction is simply Fe₃O₄ + 4C = 3Fe + 4CO. Pure (that is wrought) iron, cast iron or steel may be produced, depending upon the proportion of carbon. The chief advantages are the directness of the process, and the fact that the impurities in the fuel (sulphur, silicon, etc.) are not introduced. On the other hand it is a question whether the electric furnace can compete in economy with the blast furnace and Bessemer converter.

Alundum, the trade name for artificial corundum, is an abrasive made by a process due to C. B. Jacobs. Bauxite, a natural hydrated alumina, the same material as used in the Hall aluminum process, is calcined to drive off the water and then fused in an electric furnace using 80 volts and 2,000 amperes of alternating current. The mass is allowed to cool and then broken up, having a blue or red color and being of the nature of sapphire and ruby, in fact it is chemically identical with these gems. It makes excellent emery wheels, emery paper, etc.

Nitrogen and Oxygen Compounds are produced by the electrical process of C. S. Bradley, and D. R. Lovejoy. The apparatus consists of a cylindrical chamber through which a number of electrodes, EE, are introduced as illustrated. The ends of the radial arms AA carried by a revolving spindle S pass very close to the electrodes. A pressure of 6,000 to 8,000 volts maintained by the generator G, between the arms and the electrodes, produces arcs 4 to 6 inches long that are drawn

ELECTRO-CHEMICAL SERIES — ELECTRO-CHEMISTRY

momentarily. The current is unidirectional, but being pulsating, an induction coil C in series with each electrode, cuts the current down to about .005 ampere per arc. There are 180 stationary electrodes in each chamber, and as the arms revolve 500 or more times per minute, at least 18,000 arcs are formed in each chamber in that time. Ordinary air, after being dried, is passed through the chamber, where the arcs cause a certain percentage of the nitrogen and oxygen to combine. This compound absorbed in caustic soda forms sodium nitrite or nitrate, with potassium hydrate it forms potassium nitrite or nitrate, and by absorption in water nitric acid may be produced.

Ozone is produced in chambers through which a silent electric discharge is caused to pass from a static electric machine, induction coil or very high voltage transformer. If air circulates through the chamber a certain portion of its oxygen is converted into ozone.

Organic Compounds, such as dyestuffs, vanillin, iodoform, chloroform, are also produced electrically. See ELECTRO-CHEMISTRY; ELECTRIC FURNACES; METALLURGY.

F. B. CROCKER,
Columbia University.

Electro-chemical Series, the arrangement of a number of chemical substances in the order of their affinity for the positive or for the negative pole of a battery.

Electro-chemical Society. The American Electro-chemical Society was founded in Nov. 1901, at Philadelphia. The second general meeting was held at Niagara Falls during October 1902, and the third in New York in 1903. The society has now about 500 members. It was organized to promote the interests of theoretical and applied electro-chemistry and electro-metallurgy, and its influence has already been felt in that new and rapidly growing industry. Its membership includes most of the prominent electrical engineers and electro-chemists in this country.

Electro-chemical Telegraph, a telegraph which records signals upon paper imbued with a chemical solution, which is discharged or caused to change color by electric action. The first was that of Bain, in 1845, then followed those of Bakewell, Gintl, and Bonelli.

Electro-chemistry, that branch of chemistry in which the reactions that occur are instituted or maintained, either directly or indirectly, by electrical agencies. The electric furnace (q.v.) affords an example of the indirect application of the electric current to the manufacture of chemical substances; the adjective "indirect" being applied in this case, because in most of the uses to which the electric furnace is put, the current does not itself perform chemical work, but merely serves to produce the high temperatures that are essential to the chemical reactions that are desired. The highest temperatures that were known previously to the invention of the electric furnace, were those that prevail in the flame of the oxy-hydrogen blow-pipe. The temperature that is attainable by the combination of oxygen and hydrogen, however, is limited by the fact that water-vapor (which is the product formed by the combination of these gases) has a definite, though high, temperature of dissociation, above which it cannot exist as water-vapor,

but is resolved again into a mixture of hydrogen and oxygen. Hence this temperature of dissociation cannot be exceeded by the oxy-hydrogen blow-pipe flame, since the gases cease to combine when it is attained. In the electric furnace no such theoretical limit exists. The heat is produced, here, by the conversion of the electrical energy into heat energy; and so long as the generation of heat within the furnace exceeds that which is lost by radiation in other ways, the temperature will continue to rise without limit, or until some essential part of the furnace itself melts or volatilizes. Calcium carbide is formed, at these high temperatures, by the direct union of carbon and lime, and is now made, commercially and in large quantities, by this process; but the combination does not occur at the comparatively low temperature of the oxy-hydrogen flame. Carborundum (carbide of silicon) is also made in the same way.

The direct action of electricity in promoting chemical combination is exemplified by the "ozonizer," which consists of a pair of glass tubes, placed one within the other, and separated by an annular space. Coatings of tin-foil, or of something equivalent to it, are applied to the inner surface of the inner tube, and also to the outer surface of the outer one; the apparatus being then connected with the terminals of an induction coil, after the manner of a Leyden jar. The annular space between the two tubes is thus exposed to a rapid alternation of electric stresses, though no actual sparking takes place through it. Gases which ordinarily show no tendency to combine with each other often will do so with greater or less readiness when mixed in suitable proportions and exposed to the alternating electric stress (known, technically, as the "silent discharge") in the annular space between the two tubes. The apparatus is called an "ozonizer," because it is chiefly used for the production of ozone from oxygen, or from air; but it has also been used, in the laboratory, for the production of many other substances. As an example of the singular power of the silent electric discharge to effect syntheses, it may be noted that hydrogen and carbon dioxide, when mixed in the proper proportions, combine directly under its influence, with the formation of formic acid. $\text{CO}_2 + 2\text{H} = \text{H.CO.OH}$. The combination does not occur explosively, but, like most of the other combinations under the influence of the silent discharge, it progresses quite slowly and uniformly.

The synthesizing action of the silent electric discharge has a great theoretic interest, but it has never been found to be of any particular importance for the commercial production of chemical substances. Electrolysis of dissolved salts has been found to be far more promising, and a corresponding amount of attention has been given to it. (See ELECTROLYSIS.) A large part of the copper of commerce is now refined by electrolysis, and practically all of the aluminum that is produced is reduced to the metallic form by this same method. (See ALUMINUM; COPPER; ZINC.) Common salt (sodium chlorid) is electrolyzed in large quantities in connection with the manufacture of bleaching powder (q.v.) and caustic soda; the chlorine that it contains appearing in the form of bubbles at the anode, while the sodium goes to the cathode, where it combines with a molecule of water at the instant of its liberation, generating sodium hydroxid, or

ELECTRO CHRONOGRAPH — ELECTRO-DYNAMICS

caustic soda. The free chlorine thus obtained is used in the manufacture of bleach, or of chlorate of potassium or chlorate of sodium; and the caustic soda that is simultaneously formed at the cathode may be recovered and brought into marketable form. In mills where wood pulp is manufactured in large quantities it is not uncommon to meet with auxiliary electro-chemical plants for the manufacture of the bleach liquor that is needed for whitening the pulp; but in these plants no attempt is usually made to recover the caustic soda, nor to utilize it in any way, since the pulp-mills are often far from any market at which the soda could be sold, and the freight rates would make its recovery unprofitable. In regions that are more favorably situated, however, caustic soda is now produced by the electrolytic method in vast quantities. Barium hydrate is also manufactured in quantity by electrolysis, and its market price has been materially reduced, in consequence, within the past few years. Great attention has been paid to the electrolysis of organic substances in recent times, especially in Germany, and results that are of much value have already been obtained. Several of the great chemical works of Germany and Switzerland are now preparing certain of the coal-tar colors by electrolysis (q.v.) on a commercial scale; but the details of the processes are not made public. Goppelsroeder has given special attention to the electrolytic preparation of these bodies, and with an encouraging measure of success. Among his results of fundamental importance we may specially note the preparation of alizarin by the electrolysis of anthraquinone and caustic potash, and of aniline black (together with other coloring matters) from aniline.

The literature of electro-chemistry and of electrolysis is already extensive, and periodicals devoted to the subject, as well as societies for its study and further development, exist in several countries. The American Electro-Chemical Society, which now includes most of the workers in this field in the United States, was organized 1 Nov. 1901 in Philadelphia. Some idea of the magnitude to which the electro-chemical industry has grown may be had from the fact that the value of the annual output of electro-chemical products, in the United States alone, exceeds \$100,000,000. Germany is second, with an annual output of more than \$15,000,000.

More or less information on the subject of electro-chemistry and electrolysis may be had in any work on physical chemistry. A valuable and suggestive mass of material, bringing the subject down to about 1889, will be found in Tommasi's 'Traité d'Electrochimie.' An excellent elementary exposition of the principles of electro-chemistry is given in Lüpke, 'The Elements of Electro-Chemistry Treated Experimentally'; and Löb's 'Electrolysis and Electro-synthesis of Organic Compounds,' translated into English by H. W. F. Lorenz, is equally good for the special applications to organic chemistry. See ELECTRO-CHEMICAL INDUSTRIES.

Electro Chronograph. See CHRONOGRAPH.

Electrocides, the amber islands of Greek mythology, at the mouth of the river Eridanus. The name was applied also to the islands on the northern coast of Europe.

Electroculture of Plants, the employment of electric light in agriculture and horticulture.

It was determined at the Agricultural Experiment Stations of Cornell University and of West Virginia, in experiments made with the arc and the incandescent lights, respectively, that certain crops are forwarded by the light. The most remarkable instance is that of lettuce, which was brought to maturity from 5 to 10 days earlier than other plants grown in the same house, and under otherwise identical conditions. This discovery has led to the commercial application of the arc light, if not of the incandescent also, to the forcing of lettuce under glass in several of the larger New England forcing houses with the result that a gain of about three weeks' time is calculated upon for the season, thus enabling the gardener to devote his benches to one more crop than formerly, or to follow his lettuce crops with cucumbers, the favorite successor, much earlier than would otherwise be possible. Several flower crops, such as Easter lilies and sweet-peas, have been experimented upon with the result that they were forced into bloom several days in advance of others grown without the stimulus. In such cases the plants are always grown without the light until within about a month of maturity, when the light is applied for about half the night. It has been found that unless the light pass through a glass globe or pane there is a noticeable "scorching" of the foliage or flower. It is concluded that this is due to the action of the ultra-violet rays of the spectrum rays, which do not pass through the glass.

Consult various bulletins of the Massachusetts Hatch, Cornell University, and West Virginia, Experiment stations. See ELECTRIC VEGETABLE GARDENING.

Electrocution. See ELECTRICITY, CAUSE OF DEATH BY.

Electrode (Greek, *hodos*, "a way"), a term introduced by Faraday to denote the wires or other terminals by which electricity either enters or leaves a body which is undergoing electrolytic decomposition, in order to avoid an implied theory connected with the use of the older terms pole, positive pole, negative pole. He called the electrode at which the current enters the anode (*ana*, upwards), and the electrode at which the current leaves the electrolyte the cathode (*kata*, downward). The two latter terms have now been introduced in metallurgic practice; and the term electrode has become common in the more extended sense of the way by which electricity enters or leaves an instrument.

Electro-dynamics, that branch of electrical science which treats of the attractions and repulsions exhibited between wires or other conductors along which currents are passing. If two wires are parallel they will attract each other when currents are passing the same way along them both, and will repel each other when the currents are opposite. If the wires are inclined to each other at any angle there is not only an attraction or repulsion but a still more marked tendency to rotation which is not satisfied till the wires have become parallel and the currents flow in the same direction along them both. When there are only two straight wires these forces are feeble and require delicate apparatus for their exhibition, but by employing

ELECTRO-DYNAMOMETER — ELECTROLYSIS

coils of wire the forces are multiplied and an instrument constructed on this principle called the electro-dynamometer has been much employed for the measurement of currents. The whole science of electro-dynamics is due to Ampère, who discovered its main facts and reduced them by ingenious experiments, combined with very abstruse reasoning, to a single mathematical formula which includes them all.

Electro-dynamometer, an instrument used for the measurement of electric currents by means of the mechanical forces which they exert on each other. It contains two coils of wire, one fixed and the other movable; the latter being either larger or smaller than the other so as to be able to pass either outside it or through it. The coils are set up in vertical planes at right angles to each other; they have a common centre and round the common central diameter of the coils the movable one can revolve. The terminals of the movable coil dip in cups of mercury, one of which is in connection with one end of the fixed coil and the other with one of the binding screws of the instrument. The other binding screw is in connection with the other end of the fixed coil. Hence, when the two binding screws are connected with a battery or other source of electricity the current has to pass through both coils. Its effect is exhibited by a tendency in the movable coil to set its plane in coincidence with that of the fixed coil, and in such a manner that the current will circulate the same way round both coils. This tendency is resisted by mechanical means provided for the purpose—usually by the torsion of a wire from the end of which the movable coil hangs, and the measurement is usually made by applying torsion till the planes of the two coils are at right angles. See ELECTRIC ALTERNATING CURRENT; ELECTRIC DIRECT CURRENT.

Electro Kinetics. See ELECTRIC DIRECT CURRENT; ELECTRIC ALTERNATING CURRENT; ELECTRICITY.

Electrolysis, in the strict sense, is the resolution of a fluid into its proximate constituents by the direct chemical action of the electric current; but the word is now commonly applied to all chemical operations, whether analytic or synthetic, which are performed by the direct action of the current. The phenomena that occur in the electric furnace (q.v.) are often incorrectly said to be "electrolytic"; but in most cases they are not so, electricity being used, in this instance, merely as a means for the production of high temperatures. Most of the chemical reactions that are observed in the electric furnace would occur equally well without the use of electricity, if the same high temperatures could be realized by other means; though in some cases, as in the reduction of metallic aluminum by the Hall process (see ALUMINUM), the fundamental operations really are electrolytic, and the high temperature is required merely to keep the electrolyte in the fluid state. The first recorded observation of a distinctively electrolytic action was made in 1800 by Nicholson and Carlisle, who observed that when the terminal wires of a galvanic battery are immersed in water, bubbles of gas arise from

them. The correct explanation of this phenomenon was shortly afterward given by Sir Humphry Davy, who carried out an exhaustive series of experiments which laid the foundations for the practical knowledge of electrolysis that we have to-day. Davy demonstrated the tremendous importance of the electrolytic method of analysis, by applying it to study of the alkaline earths and the caustic alkalies. The nature of these substances was not previously understood; but he proved them to be the oxides of previously unknown metals, and prepared the metals themselves in the free state. By passing the electric current through melted potash, for example, he found that bubbles of free oxygen gas were liberated at one of the electrodes, while silvery globules of what is now known as potassium appeared at the other electrode. A few days later he isolated the metal sodium in the same manner, by the electrolysis of soda; and he succeeded, afterward, in demonstrating the compound nature of lime and magnesia also, by the aid of the electric current. As may be imagined, the new method aroused the keenest interest in the scientific world. Napoleon, then at the zenith of his power, offered valuable prizes for discoveries along the same lines, and had large voltaic batteries constructed, in order that French investigators might have every opportunity to carry on the work. The two great Swedish scientists, Berzelius and Hisinger, discovered many new phenomena, and elaborated a general theory of the constitution of chemical substances, based largely upon their behavior under the action of the electric current; and Faraday (q.v.) established the fundamental quantitative laws that hold true in electrolytic decomposition.

Some slight evidence has been adduced which indicates that in certain cases the passage of electricity through solids may be accompanied by slight chemical changes of an electrolytic nature, and phenomena allied to those of electrolysis have been observed in connection with high-tension electrical discharges through gases (see Thomson, 'Recent Researches in Electricity and Magnetism,' chapter 2 and appendix); but in general, electrolysis is observed only in liquids. All liquids may be divided into three classes, according to their behavior when the attempt is made to pass electricity through them. In the first class belong mercury and the other molten metals, which conduct the current readily, and without any noticeable chemical effects. In the second class belong such substances as carbon disulphid and absolute alcohol, which do not conduct the current at all, and hence are not subject to decomposition by it. Absolutely pure water probably belongs to this class, though it becomes a conductor when the smallest quantities of certain impurities are present. Water that is ordinarily called "pure" conducts electricity fairly well, but its conductivity falls off as the purity increases, and Kohlrausch and Heydweiller have shown that water that is distilled in a vacuum, and collected in a glass vessel which has been kept full of distilled water for 10 years in order to dissolve out all the soluble constituents of the glass, has a conductivity almost too small to be measured. The third class of liquids includes all those (such as aqueous solutions of the various metallic salts) in which electric conduction is always accompanied by a definite chemical change. In the

ELECTROLYSIS

present article attention will be confined to this third class, whose constituents are known as "electrolytes," and in which the current is said to flow by "electric conduction."

It is necessary, in the discussion of electrolytic phenomena, to distinguish between the primary effects of the passage of the electric current through an electrolyte, and the various secondary effects that may also occur; and while it is not always easy (nor even possible), in actual work, to determine, definitely, what the primary effects are, one or two cases may be cited which will serve to illustrate the difference between primary and secondary effects sufficiently for present purposes. If a current of electricity is passed through melted chloride of lead, PbCl_2 , the primary effect of the electrolysis is the resolution of the chlorid into its constituent elements, in accordance with the equation $\text{PbCl}_2 = \text{Pb} + 2\text{Cl}$, metallic lead being deposited upon the cathode. If carbon electrodes are used, free chlorine will also appear at the anode; but if platinum electrodes are used, little or no free chlorine will be obtained, because the gas will combine with the metal of the anode in this case, with the formation of platinum tetrachlorid. The combination of the chlorine with the platinum is an example of secondary action. Again, in the electrolysis of sulphuric acid, H_2SO_4 , it is known that the primary effect is the resolution of the acid into hydrogen and the radical "sulphion," SO_4 , in accordance with the equation

The hydrogen goes to the cathode, where it is set free. The sulphion goes to the anode, but it is not capable of existence in the free state, and hence some secondary reaction is inevitable. If the acid is dilute, and the anode is of platinum, the sulphion combines with water at the instant of its liberation, according to the equation $\text{SO}_4 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4 + \text{O}$. In this case, therefore, the effect of the secondary action is to regenerate a molecule of sulphuric acid, and simultaneously set free an atom of oxygen; and the evident products of the electrolysis are merely hydrogen and oxygen, which appear at the cathode and anode, respectively. If the acid is concentrated instead of dilute, the secondary action just described will still occur to some extent so long as the acid is not absolutely anhydrous, but free sulphur dioxid is also liberated at the anode in this case; and finally, under certain conditions, sulphur itself may be obtained at the cathode. The secondary chemical changes that occur in an electrolytic cell depend upon the nature of the electrolyte, upon the concentration of the solution, upon the temperature, and upon the strength of the current to which the primary chemical effects are due. They are often complicated and of an unexpected nature; and it is to the study of these secondary changes, under varying conditions, that industrial electrolytic chemistry must look for its further advancement.

No primary chemical changes whatever are to be observed, in an electrolytic cell, save at the electrodes; though secondary changes may occur elsewhere, on account of the diffusion of the immediate products of decomposition through the liquid of the cell. The primary changes do not depend in the smallest degree upon the size of the electrodes, nor upon any other factor save the total quantity of electricity that passes

through the cell. If a series of cells, containing electrodes of various sizes and filled with a given solution in different states of concentration, be placed simultaneously in the same circuit, so that the same identical current traverses them all, the primary products of decomposition will be the same in all, both in nature and in quantity. Moreover, if the same experiment be repeated when the several cells are filled with solutions of diverse natures, the primary products will necessarily be different from one another in kind, but when their quantitative relations are examined, it is found that they are liberated in precisely equivalent proportions. For example, if one cell contains chlorid of sodium and another contains nitrate of silver, then the quantity of chlorine liberated in the first cell is precisely sufficient to unite with the metallic silver liberated in the second one, so as to produce chlorid of silver without excess of either chlorine or silver. This statement needs one simple qualification, however, before it can be applied universally. If the two cells considered contain mercuric nitrate, $\text{Hg}(\text{NO}_3)_2$, and mercurous nitrate, HgNO_3 , respectively, then for every ounce of mercury that is deposited from the mercuric salt, two ounces will be deposited, simultaneously, from the mercurous salt. Obviously the quantities of Hg and of NO_3 that are liberated in the two cases cannot both be the same; and it is the NO_3 , and not the Hg, which is liberated in equal quantities. In general, the "chemical equivalent" of an element is defined as the atomic weight of the element, divided by the valency that the element has, in the compound under consideration; and the quantities of the various elements that are liberated by a given quantity of electricity are proportional to the "chemical equivalents" of the elements, as they occur in the compounds that are submitted to electrolysis, rather than to the "atomic weights" of these elements. The number of grams of an element that are liberated, electrolytically, by one C. G. S. unit of electricity, is called the "C.G.S. electro-chemical equivalent" of that element. The electro-chemical equivalent of silver is known by experiment to be about 0.01118; and the electro-chemical equivalent of any other element may be found from this by simple proportion, as explained above. For many purposes it is more convenient to know what weight of a given element will be deposited in one minute, by a current whose intensity is one ampere. This is given, in the accompanying table, for the more important elements. The elements are here divided, for convenience, into those that are electro-positive, and those that are electro-negative; the former being those that usually appear at the cathode, and the latter those that usually appear at the anode. This classification is not very valuable in the case of complicated compounds, but it answers for the simpler ones. The data given in the table refer to the primary products of decomposition; but it is sufficiently evident that they apply equally well, so long as the visible product of the decomposition is all of one kind, whether it is primary or secondary. In the electrolysis of sulphuric acid, for example, "sulphion" is the primary product at the anode; but sulphion is incapable of independent existence, and the only visible product at the anode is oxygen, so long as the acid is sufficiently dilute. In this case the quantity of oxygen that is liberated can be

ELECTROLYSIS

computed precisely as though the oxygen were itself the primary product. When, as in the electrolysis of concentrated sulphuric acid, more secondary products than one are obtained, the

case is more involved. In general, however, we must remember that it is only with reference to the primary products that the electrolytic nature of the decomposition need be considered; for the secondary reactions are merely those of ordinary chemistry.

The most generally accepted theory with regard to the nature of electrolytes is that which is known as the "ionic theory," and which teaches that a salt whose solution is capable of electrolysis becomes more or less completely dissociated when it is dissolved, the respective parts into which its molecules subdivide being known as "ions." This aspect of the phenomena of solution is considered in the article SOLUTION (q.v.), and in the present place we need dwell only on those features of the ionic theory which have an immediate bearing on the subject of electrolysis. The ions into which the electrolyte is resolved, upon solution, are supposed to be associated with definite charges of electricity, which cling to the ions so long as the dissociation persists, and can only be neutralized by causing the ions to come together again so as to re-form a molecule of the original salt, or to enter into other chemical combinations with one another; neutralization being effected, in such cases, by the actual discharge of the equal and opposite electricities into one another, as the re-combining ions come together. What the ions are, into which a given salt dissociates when it is dissolved, can only be discovered by inference from certain kinds of experiments for which reference must be made to the books cited in the article SOLUTION. Our knowledge on this point is still far from complete, but we know what the ions are in most of the simpler electrolytes. When potassium hydroxid, KOH, is dissolved in water, it becomes dissociated, or "ionized," into the ions K and OH. At first thought it appears to be impossible to admit that potassium, which has so great an affinity for water, can exist in the free state in a solution; but it must be remembered that the potassium

"ion" differs from the ordinary potassium atom by the possession of a definite and considerable electric charge, which modifies its chemical behavior profoundly. As the solution is concentrated by evaporation, the potassium ions and the hydroxyl ions (OH) come together, discharge into each other, and unite to form potassium hydroxid, KOH, which is deposited in the solid form. (Some of the hydroxid remains in solution as such, the dissociation never being complete except in exceedingly dilute solutions; but this point is not essential to our present purpose, and for its further elucidation reference must be made to the article SOLUTION.) In the ionized state, the potassium is charged positively and the hydroxyl negatively; and, in general, any ion which appears at the cathode during electrolysis is charged positively in the free solution, and any ion which appears at the anode is charged negatively. Moreover, the phenomena of electrolysis prove that any given ion is always associated with the same identical charge of electricity, no matter what the salt may have been from which the ion was obtained, provided the ion has the same valency in each of the salts that are compared. The potassium ion in a solution of potassium chlorid, for example, carries precisely the same charge as the potassium ion in a solution of potassium nitrate, or of potassium carbonate. We may therefore regard the free ions in a solution as so many little buckets filled with electricity, all the buckets having identically the same capacity.

According to this view, the ions act as mere carriers of electricity, and electrolysis is not simply an accompaniment of conduction through an electrolyte, but the very means by which this conduction is effected. The electric circuit in which the electrolysis occurs may be likened to a brook. If the metallic circuit is interrupted by the insertion of a solution of some kind, the solution so inserted corresponds to a dam in the brook, through which no water can pass by direct flow. The analogy is fairly complete when the solution does not contain free ions, for then it will not act as an electrolyte, and no current can pass. Sugar, for example, does not dissociate to any appreciable extent when it is dissolved, and hence a solution which contains nothing but pure water and pure sugar cannot conduct electricity, and merely acts as an impassable barrier to the current. When the solution contains a salt (such as sodium chlorid) which is largely or wholly dissociated, the free ions act like a molecular bucket brigade, passing the water across the dam in the brook, or the electricity across the gap between the two electrodes in the electrolytic cell. In the electrolysis of copper sulphate, for example, the phenomena are as follows: The formula of the sulphate is CuSO_4 , and the free ions in the solution (and hence also the primary results of the decomposition) are copper and "sulphion," SO_4 ; the copper ion being charged positively, and the sulphion ion negatively. The electrodes that are immersed in the electrolytic cell are also kept continuously charged by the battery (or dynamo) with which they are connected; the cathode being negative and the anode positive. The positively charged copper ions in the solution are therefore attracted by the negatively charged cathode, just as a positively charged pith ball is attracted by a negatively charged body in the air. Hence they move towards the

ELECTROLYSIS — ELECTRO-MAGNETIC THEORY OF LIGHT

cathode, and when they reach it they discharge their electricity upon it, thereby ceasing to be ions, and becoming transformed into atoms of ordinary copper, which are perforce deposited upon the cathode. The sulphion ions simultaneously move towards the anode, upon which they discharge the negative electricity that they carry. The ionic charge is essential to the continued existence of the sulphion, however, and when this charge is lost, the sulphion must either break up into sulphur dioxide and free oxygen, or else combine with some other substance to form a new compound. If the anode is made of platinum or carbon, the sulphion usually combines with a molecule of water with the liberation of free oxygen, as already explained in connection with the electrolysis of dilute sulphuric acid; but if the anode is made of a material that is less resistant to chemical action, the sulphion may combine with the anode itself instead of with a molecule of water. For example, when the anode is of copper, the sulphion, at the moment that it loses its electric charge, combines with an atom of the anode so as to form a molecule of copper sulphate.

The solvent, according to this theory, is to be regarded as an insulator, through which the electricity is passed by the ionic bucket-brigade. There is no real "conduction" through an electrolyte; but the positive charges that the ions bring to the cathode diminish the charge of the cathode so that more negative electricity must flow to it from the battery (or the dynamo), in order to maintain its potential; and, similarly, the negative charges that the ions carry to the anode require a constant supply of positive electricity from the battery, in order that the potential of the anode may be maintained. The general effect upon the circuit, therefore, is the same as though there were an actual conduction of electricity through the electrolyte. (For a further elaboration of the ionic theory of electrolysis, consult Whetham, 'Solution and Electrolysis.' See also SOLUTION.)

By a detailed study of the secondary chemical actions that occur when salt solutions are electrolyzed, it has been found to be possible to isolate many of the metallic elements by electrolysis, when they are present in a mixed solution; and a promising system of "electro-chemical analysis" has been based upon this fact. Copper may be separated from cadmium, for example, by electrolyzing a solution of their mixed salts, in which free nitric acid is present, the copper being obtained in the metallic form, while the cadmium remains in solution. If the same solution is neutralized by potassium hydroxide, and then electrolyzed after the addition of potassium cyanide, the cadmium is deposited, while the copper remains in solution. The successful application of the principles of electrolysis to analysis requires an extensive knowledge of the secondary reactions that occur at the electrodes, however, as well as a full understanding of various practical conditions that must be carefully attended to. For these consult: Smith, 'Electro-Chemical Analysis' (1903), together with the references therein given. See ELECTRIC FURNACES; ELECTRO-CHEMICAL INDUSTRIES; ELECTRO-CHEMISTRY; ELECTRON; SOLUTION.

Electrolysis of Gas and Water Mains, the eating away of metal in underground pipes

caused by fugitive electric currents. Electric street railway systems are largely responsible for such electrolysis. The subject first came under discussion among electricians in 1892, when the matter was brought to public attention by various gas and water companies. Metal in water mains frequently becomes so badly decomposed that the pipes burst and great damage results. The remedy for the evil is to provide ample and unfailing means for the control of stray electric current and its return to the power house.

Electrolyte, a compound which is decomposable, or is subjected to decomposition, by an electric current. See ELECTRIC STORAGE BATTERY.

Electro-magnetic Engine, a machine in which the motive power is derived from electromagnets excited by an ordinary voltaic battery, or by the more modern secondary battery. In Froment's engine, a cylinder furnished with iron bars or armatures, turned in front of the poles of an electro-magnet, the current being cut off automatically as each bar passed the poles. Most modern dynamo-machines can be used as motors, and in this capacity can be employed for railways, street cars, and vehicles.

Electro-magnetic Force, the induction current in an electro-magnetic machine; the magnetism which it excites; the attractive force; and the lifting power which it possesses.

Electro-magnetic Induction. See INDUCTION.

Electro-magnetic Telegraph, a signaling, writing, printing, or recording apparatus, in which the impulses proceed from a magnetic force developed by voltaic electricity. The principle is that a mass of soft iron is rendered temporarily magnetic by the passage of a current of electricity through a surrounding coil of wire. It differs from the electric telegraph properly considered, and also specifically from the magneto-electric telegraph. The earlier electric telegraphs were all what their name implies, and not electro-magnetic. The pioneers in its discovery were Sömmering in 1808, and Prof. Coxe, of Pennsylvania, about the same year. Then followed Oersted in 1820. In 1832 Prof. Morse began to devote his attention to the subject of telegraphy, and in that year, while on his passage home from Europe, invented the form of telegraph since so well known as "Morse's." A short line worked on his plan was set up in 1835, though it was not until 20 June 1840, that he obtained his first patent. His first idea was to employ chemical agencies for recording the signals, but he subsequently abandoned this for an apparatus which simply marked on strips of paper the dots and dashes composing his alphabet. In 1840 Wheatstone, whose attention seems to have been drawn to telegraphy about 1834, patented a dial instrument, on which, however, he afterward adopted several modifications.

Electro-magnetic Theory of Light, a theory propounded by J. Clerk Maxwell, that light is an electro-magnetic phenomenon. Though the theory has found able advocates, it has not received general acceptance among physicists. The discovery of the Roentgen rays tends to establish the correctness of the theory.

ELECTRO-MAGNETIC WATCH — ELECTRON

Certain phosphorescent light has, like the X-rays, the power of penetrating bodies opaque to ordinary light, which seems to furnish a connecting link between ordinary light and the Roentgen rays, and the discovery by Marconi, that electric vibrations can be projected through space in straight lines, and be reflected and refracted like light—indeed, made to conform to all of the manifestations characteristic of light—seems to leave little room to doubt that electricity and light have a common origin. See WIRELESS TELEGRAPH.

Electro-magnetic Watch. See ELECTRIC SIGNALING.

Electro-magnetism. Magnetism can be strongly excited in soft iron, by means of an electric current. For this purpose the bar to be magnetized is surrounded by a helix consisting of several coils of insulated copper wire wound upon a bobbin. The circuit being closed, the bar becomes powerfully magnetic and may be made to attract a number of nails. On breaking the circuit the magnetism disappears, and the nails at once fall away. The magnetism thus called forth is termed "electro-magnetism." The bar magnetized in this way becomes a perfect magnet; in other words, it acquires a north and a south pole. The polarity of the bar depends upon the direction of the current, and also upon the twist of the wire in the helix. With the same kind of helix, that is, whether the twist be from left to right or right to left, the polarity is reversed by changing the direction of the current. Again keeping up the same direction in the current, the polarity is reversed by changing the helix.

Electro-magnets. A French inventor, Ampère, discovered the permanent magnetization of steel needles, and the temporary magnetization of iron filings by means of the electric current. He adopted the method of placing the steel needle or bar within a coil or helix of copper wire, and in doing so he found that if the helix was wound from right to left over the needle, as at the end of the needle at which the positive current entered became the north marked pole, but if wound from left to right the end at which the current entered became the south pole. M. Pouillet constructed an electro-magnet for the Faculty of Sciences at Paris, consisting of two horseshoes, each wrapped with 10,000 feet of copper wire, and so arranged that the poles of contrary names should be in contact. With a current of moderate intensity this apparatus supported a weight of many tons. A small horseshoe electro-magnet with a core of $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter, and 5 or 6 inches long, having three or four layers of covered wire of the thickness of bell wire twisted around each limb, will lift 10 or 12 pounds when excited by only a single pair of Smee's battery, with plates 4 inches square. In constructing an electro-magnet the use of cast iron must be avoided, as it partakes of the nature of steel; malleable iron should be used; and even the purest and softest that can be made always retains a certain amount of attractive force after the current ceases. When a rapid motion of the armature is required the effect of this residual magnetism may be neutralized by covering the surfaces of contact with varnish or thin paper. The principle of the electro-magnet is employed

in the dynamo and motor for the purpose of producing a powerful magnetic field in which the rotation of the armature takes place. For this purpose the whole or a portion of the armature current may be employed in the field magnets for the purpose of exciting the field. See MAGNET; ELECTRO-MAGNETISM.

Electro-massage. See ELECTROTHERAPEUTICS.

Electro-metallurgy and Electric Smelting. See ALUMINUM; COPPER; GOLD; METALLURGY; PLATINUM; SILVER; ZINC.

Electrometer, an instrument for measuring differences of electric potential between two conductors through effects of electrostatic force, and not, as in galvanometers of all varieties, through certain electro-magnetic effects of electric currents produced by them. See ELECTRICITY.

Electro-motive Force, a term used in connection with batteries and other sources of electric supply to denote the difference of potential existing between the plates or terminals, in consequence of which there is a tendency for a current to flow when the plates are connected by a conductor. See BATTERY; ELECTRICITY; MOTOR; PRIMARY BATTERIES.

Electro-motive Series, applied to the metals in a voltaic couple, metals so arranged as to have the most electro-positive at one end, and the most electro-negative at the other. Ohm's law on the subject is that the intensity of the current is equal to the electro-motive force divided by the resistance.

Electro-motograph, a name given to a peculiar telephone receiver invented by Edison. See TELEPHONE.

Electron, one of the ultimate particles of which (according to the views now tentatively held by physicists) the atoms of matter are composed. The "electron hypothesis" is still in its infancy, and years will probably elapse before its truth or falsity can be demonstrated with any degree of certainty. It teaches that the atoms, which were formerly supposed to be simple bodies that are incapable of subdivision, or bodies which at all events do not undergo division in the ordinary processes of nature, are really systems of some considerable complexity, built up of thousands of still tinier "electrons," each of which is endowed with a permanent electric charge. The definite development of the electron hypothesis originated with the study of electric discharges through highly rarefied gases. Crookes, for example, boldly took the position that the luminous streams ("cathode rays") that proceed from the cathodes of highly exhausted vacuum tubes are composed of tiny material particles that are moving away from the cathodes like storms of projectiles. In support of this view he exhibited many ingenious and beautiful experiments, in which the corpuscular torrents were caused to turn paddlewheels and heat targets to whiteness. He did not definitely commit himself to any theory as to the precise nature of the corpuscles, but he recognized them as being somehow different from the ordinary molecules of matter, and he consistently and persistently maintained that the matter in these tubes is in a "fourth state," which is essentially

ELECTRON

different from the familiar gaseous, liquid and solid states, which matter has long been known to be capable of assuming. This fourth state he called "radiant matter." His views were opposed by many competent authorities, who adhered to the view that the cathode rays are wave-like phenomena, due in all probability to the extraordinary electrical stresses that are set up in the luminiferous ether within the tubes, by the induction coil that is used to produce the discharge. As further experimental evidence has accumulated, however, the substantial correctness of Crookes' views has become increasingly evident, and the corpuscular nature of the cathode rays is now generally admitted. Numerous exceedingly ingenious experiments have been devised for determining the masses of these corpuscles (or "electrons"), and the magnitude of the electric charges that they carry; and the results are most surprising. Let m be the mass of an electron, v the velocity with which it is moving in the cathode stream, and e the electric charge that is associated with it. Then it can be shown theoretically that in a magnetic field the electron will describe a curved path instead of a straight one. If the magnetic force acts at right angles to the direction of the stream, and has an intensity H , the path of the electron will

be a circle of radius $\frac{mv}{eH}$. By observing the

actual curvature of the cathode stream under the influence of a known magnetizing force H , we can therefore find the value of the expression $\frac{mv}{e}$.

It is also known that the tendency of the magnetic force to produce curvature of the path of the electron can be neutralized by so arranging the experiment that the cathode stream is simultaneously exposed to a static electrical force of a particular intensity F , and acting in a direction that is perpendicular both to the cathode stream and to the magnetic force; the intensity, F , of the static force being such that the relation $F = Hev$ is fulfilled. By experiment, it is possible to find the numerical value of F by varying the electric force acting across the cathode stream until, under the combined influence of the static and magnetic forces, it is seen that the cathode stream is perfectly straight. When this condition is fulfilled, the equation just given shows that the velocity of the electron can be found by merely dividing the observed value of F by the observed value of H . The results obtained in this way indicate that the velocity of the electrons in the cathode stream is pretty much the same, whether the tube contains air, hydrogen, or carbon dioxide; it being about 2,500,000,000 centimetres per second (that is, about 75,000 miles), or something like one twelfth the velocity of light. The value of v being known, and the ratio of mv to e being also known by a previous experiment in which the static field is omitted and the magnetic force allowed to act alone, we are at once in

position to calculate the value of $\frac{e}{m}$ or the

charge that is carried by the electron, per unit of its mass. The numerical result so obtained (and which is sensibly the same for all gases) is that each gram of the electron's mass, in the cathode stream, carries a charge of about

10^8 coulombs. Now in electrolysis (q.v.) the ions of hydrogen carry a charge of about 96,000 coulombs per gram of their mass; or, in round numbers, 10^5 coulombs per gram. Hence if the electrons in the cathode stream have a mass equal to that of the hydrogen ion in electrolysis, they must carry an electric charge that is 1,000 times as great as that carried by the hydrogen ion; and conversely, if (as many authorities consider probable) they carry the same electric charge as the hydrogen ions carry in electrolysis, it follows that the electron has a mass only about one one-thousandth as great as that of the hydrogen ion (or atom). The reasoning given above appears to be beyond reproach, and it is substantiated by other methods of experiment that cannot be here considered. J. J. Thomson, who has been especially prominent in connection with the development of the electron hypothesis, endeavored to determine which of the alternatives suggested above corresponds with the real facts of the case. His method for doing so is described in full detail in the 'Philosophical Magazine' for December 1898, but is too technical to be given in the present article. His general conclusion is, that the charge is the same upon the electron as it is upon the hydrogen ion in ordinary electrolysis; and hence that the mass of the hydrogen atom is 1,000 times as great as the mass of an electron. It is not certain that this conclusion will be fully sustained by future investigations, because some of the assumptions and observations upon which it is based have not yet been established beyond controversy. It may yet be found that the electron and the hydrogen atoms are not greatly different in mass, but that the electron carries a far larger charge of electricity than the ion that is concerned with electrolysis. Assuming the correctness of Thomson's views, certain physicists have elaborated fascinating hypotheses as to the constitution of matter, and have even attempted to explain the genesis of the definite species of matter that we call elements. (See ELEMENT.) It is not at all improbable that matter really is of only one fundamental kind, and that we shall one day know how the elements differ from one another. It is even possible that the electron hypothesis is the key that is to unlock this secret; but the subject is still too new for any definite and valuable judgment to be passed upon this phase of it. In general, there is a tendency towards the belief that the electrons are the fundamental units of which the atoms are composed; and according to this view they may be likened to the bricks with which buildings are constructed in human architecture. The electrons of all bodies are supposed to be identical with one another, and the atoms of any two elements, such as hydrogen and iron, for example, are supposed to differ only in the number of the electrons that they contain, and in the way in which these electrons are grouped. It is known that a swiftly-moving charge of electricity would show inertia-like effects, even if it were not associated, in its motion, with any body possessing true mass. Hence it has been thought probable, by many authorities, that the inertia of matter is capable of explanation in this way, if it is admitted that atoms are really composed of electrons flying around in orbits, about a mean configuration that is essentially stable so long as it is not

ELECTRO-OPTICS — ELECTROTAXIS

subjected to external disturbances of too great a magnitude. These speculations, and others of the same sort, are given in Sir Oliver Lodge's interesting lecture "On Electrons," as published in the 'Scientific American Supplement,' beginning with the issue for 16 May 1903 (No. 1428). It is probable that the views now held upon these and other allied subjects will soon undergo a substantial modification of some sort, for it is next to impossible for the human mind to conceive of any such thing as a disembodied electric charge moving about in an orbit; and while such a description of the ultimate nature of the electron may serve well enough as a starting point upon which to base mathematical equations that shall explain the phenomena that we can observe and measure in the laboratory, it can never satisfy the craving of the physicist for a definite mental image of what is really going on in the atom. Whether such a mental image is possible or not, or whether or not it is logical to strive for its attainment, are fair questions for discussion; but it is certain that the general trend of physics has been in this direction in the past, and there is no reason to suppose that the same tendency will not be equally manifest in the future. See ELECTRO-CHEMISTRY; ELEMENTS.

Electro-optics, a branch of electrical science treating of the relation of electricity to light.

Electrophorus (Greek, *pherō*, "to bear"), an instrument for obtaining electrification by means of electrostatic induction. The following is the theory of the instrument: The brass plate, when set down on the sole, touches it only in a few points, owing to the rigidity and the unevenness of both plates. If it were then lifted it would be found to carry away from these points a faint negative charge. But the greater part of it being not in actual contact with, but only in close proximity to, the remainder of the resinous plate, which is negative, the brass plate becomes excited by induction, and when the finger is brought near, negative electricity passes from the brass plate to it (just as in the elementary experiments on electrostatic induction), positive electricity being held attracted by the negative electricity of the resinous plate. When the brass plate is raised the positive electricity is set free, and is ready to be discharged. The use of the metal form, or the tinfoil pasted below the ebonite, is to admit of perfectly free charge and discharge of the lower surface of the resinous plate when the brass plate is lifted and set down. See ELECTRICITY.

Electro-photo Micrography, the art of photographing, by means of the electric light, certain objects magnified by the microscope.

Electro-photography. See PHOTOGRAPHY.

Electrophysiology, the science which treats of electric phenomena produced through physiological agencies.

Electroplating, the covering of baser metals by means of the electric current with a coating of precious metal, such as gold, silver, or nickel. German silver, or copper and its alloys are excellently adapted to receive electroplating. The process is begun by carefully cleaning and scouring the object or article to be plated, so as

to remove all trace of oxide or other impurity from its surface and interstices. A thin film of mercury is then given to it by plunging it into a bath of nitrate of mercury; by this means the plate is more closely adhesive to the under metal. The bath of gold, silver, or nickel in which the plating process is completed contains 100 parts of water, 10 of potassium cyanide, and 1 of the cyanide of the precious metal to be applied as plating. After being suspended in this bath, and covered with a proper amount of the deposit the plated articles are withdrawn, and burnished. The further details of this beautiful process must be learned from the technical handbooks which deal with the subject. The literature of electroplating is voluminous, but Brunor's 'Practical Electroplater' is an admirable guide to the mastery of the process.

Electropoion, a mixture of sulphuric acid, bichromate of potash, and water used as the liquid for batteries in which zinc and carbon are the poles. See BATTERY.

Electropyrometer. See PYROMETER.

Electroscope. A simple form of this instrument consists of a glass phial provided with a cork; through the cork there passes a brass rod, terminated above with a small brass disk, and below with a stage from which there depend two gold or Dutch metal leaves. It is used to indicate the smallest quantity of electricity with which a body may be charged. A rubbed glass tube, for example, is brought near the metal disk; it acts by induction upon it, repelling the positive fluid, and attracting the negative fluid to the upper side; the positive fluid rushes to the leaves, and in consequence of their being similarly charged, they repel each other and stand apart. If the charge of the electrified body be very small, it may be necessary to touch the disk, in that case the electricity is conducted to the leaves and they are repelled. Thus the smallest charge of electricity may be rendered apparent. The kind of electricity with which a body is charged may be revealed by this instrument. For this purpose, while the excited glass tube is held, let the disk be touched with the finger, the positive electricity is drawn from the leaves, passes through the negative, and is led away to the ground. Let now the finger be removed, and immediately afterward the glass tube, then the negative electricity diffuses itself and passes to the leaves, which therefore diverge, being charged with the same kind of electricity. A body (whose electricity is to be ascertained) is now brought near the metal disk. If the leaves diverge farther, it indicates that more negative electricity has passed to them, and therefore the body is charged with negative electricity. If the leaves collapse, the body is charged with positive electricity.

Electrostatics is the part of the science of electricity that treats of the phenomena of electricity at rest. The terms *electrokinetics* and *electrokinematics* are also employed by the most philosophical writers on electricity; but they cannot be said to be at present in popular usage. See ELECTRICITY.

Electrotaxis. See ELECTROCULTURE OF PLANTS.

ELECTROTHERAPEUTICS — ELEMENT

Electrotherapeutics is the art of applying electrical currents to the treatment of diseased conditions. As a means for treating various forms of nerve lesion, electricity has a distinct place in the armamentary of every reputable physician; but there is little doubt that at the present time a vast army of quacks and charlatans prey upon the community, by reason of their lack of knowledge as to the precise limits within which electricity is of service. Thus, there are on the market electric belts, electric garters, electric amulets, electric rings, electric hair restorers, electric ozonizers and all sorts of electrical monstrosities which from a therapeutic standpoint have absolutely no value.

At the present time three or four types of electrical current are used in medicine: frictional or static electricity induced by a Holz machine; galvanic electricity and faradic electricity produced by chemical agencies or by mechanical devices. To this could be added the electric or X-ray and similar light-producing agents. Treatment by these latter agents is not electrical treatment, it is light treatment and will be considered under that head. The action of all the forms of electricity is closely analogous. They are marked tissue stimulants, bringing about renewed activity in the cells of the organs subjected to their influence. Electricity acts, then, as nothing more than a tonic. Its action is most manifest on the muscles and nerves. It should be applied by intelligent physicians for definite aims. It is pitifully ludicrous to see the waste of time, money, and energy expended by many sick people in the abuse of electrical toy batteries. One could better cook a dinner with a box of matches than obtain any therapeutic value from the vast number of toy batteries sold by ignorant, if not unscrupulous, dealers.

Electrotint, a method of tracing drawings, etc., for printing by the action of electricity on a copper plate. The design is drawn in some varnish not affected by acid and placed in an electro-bath, the lines being thus brought out in relief.

Electrotonus, the altered state of a nerve or muscle during the passage of a galvanic current through it.

Electrotrophism. See ELECTROCULTURE OF PLANTS.

Electrotype, a copy of a form of type, made by means of electricity. A page of the type is covered with wax, which is driven into the interstices by powerful pressure. The face of the wax mold is covered with plumbago to give it a conducting surface to which the metal will adhere. The positive pole of a battery is attached to the mold, and the negative to a copper plate, and both are placed in a bath of sulphate of copper in solution. The copper is deposited on the face of the mold in a thin film, which increases in thickness as the process continues. The shell having attained the thickness of a stout sheet of paper, the mold is removed from the bath, the shell detached and strengthened by a backing of type-metal. The back of the shell is first coated with tin, and the shell is then placed face downward on a plate, and over a bath of molten type-metal. When it has attained the requisite heat, a quantity of the metal is dipped up and floated over

the back of the shell. When cold, the plate is reduced to an even thickness by a planing-machine. For printing, it is mounted on a wooden backing. Another mode of obtaining electrotype plates from a letter-press form is by a mold of gutta-percha, brushed with graphite and immersed in the electro-plating bath. Gutta-percha is also used for obtaining intaglio molds and then cameo impressions from woodcuts, for printing. See also ELECTRO-CHEMISTRY, INDUSTRIAL; PHOTO-ENGRAVING; PRINTING.

Elec'trum, a substance mentioned by Greek and Latin writers, with regard to the nature of which there has been much discussion. The term was used with different meanings; it originally meant gold, and was then applied specially to native gold, containing quantities of silver, copper, and other metals. The term employed for this native alloy was transferred to the artificial alloy of gold and silver, afterward made, and was also applied to amber on account of its color and inferior lustre.

Elegy, properly, a poem of mourning. The Greeks and Romans, however, employed the term to denote a poem written in elegiac verse, whatever its character. This elegiac verse was the distich, consisting of the hexameter alternating with pentameter. In modern times the term elegy is usually applied to any serious piece in which a tone of melancholy pervades the sentiments, as in Gray's 'Elegy Written in a Country Churchyard.'

Elegy Written in a Country Churchyard, a poem by Thomas Gray, and published in 1751. Its sincerity and simplicity of thought and language made it immediately popular, and it rapidly passed through a number of editions, and has since been often reprinted. It is thought that the churchyard is that of the parish church at Stoke Pogis.

El'ement, in chemistry, a substance that cannot be decomposed into other substances. Something like 77 different substances are now admitted by chemists to be elements, and a number of others are tentatively assumed to be so, until further evidence, for or against their elemental character, is accumulated. (A list of those that are now admitted is given under ATOMIC THEORY.) Much speculation has been indulged in, concerning the fundamental structural differences that subsist between the atoms of the different elements, but no universally acceptable explanation has yet been offered to account for the fact that the thousands of compounds that have been studied are all composed of so small a number of essentially different constituents. The alchemists believed that every apparent "element" can be modified, or "transmuted," into every other one, and much labor was expended in the effort to transmute the baser metals into the "nobler" or more valuable ones. We now know that the problem of transmutation, if it is capable of solution at all, is at any rate far more serious than it was believed to be in the early history of chemistry. But there are numerous indications which suggest a relationship among the substances that are now accepted as elements, and it may yet prove to be possible to transform lead into gold, or tin into platinum. For some years past Sir William Crookes has been a consist-

ELEMENTAL SPIRITS—ELEPHANT

ent advocate of the theory which teaches that all matter is fundamentally the same, and he has shown that some of the "elements" can be resolved, by fractionation, into substances which exhibit spectra that differ from one another in a marked manner, any two consecutive members of the series showing close similarity in their spectra, while the extreme members of the series are totally dissimilar. (See his lecture before the Berlin Congress of Applied Chemistry, entitled 'Modern Views on Matter,' in 'Science' for 26 June 1903.) The theory of matter which is in favor at the present writing teaches that all atoms are composed of electrons (q.v.), which are all alike, but which are grouped together in various ways, and in various numbers, to form the atoms of the elements. If this view stands the test of further research, the possibility of transmuting the elements into one another may not be altogether fanciful. The newly discovered element radium (q.v.), which appears to possess the singular power of continuously emitting streams of free electrons, occurs in nature in certain varieties of the mineral uraninite. It is notable that the inert gas helium (q.v.) also occurs in this same mineral, though it appears to be present in the free state, and never in actual chemical combination. It has been suggested that we are here face to face with a real case of transmutation of elements, the electrons that are emitted by the radium being slowly built up, within the uraninite, into new systems, which are nothing less than atoms of helium. See MOLECULAR THEORY; PERIODIC LAW; RADIATION; RADIUM.

Elemental Spirits, beings who, according to the popular belief of the Middle Ages, presided over the four elements, living in and ruling them. The elemental spirits of fire were called salamanders; those of water, undines; those of the air, sylphs; and those of the earth, gnomes. Paracelsus wrote a treatise upon them, and they play a part in Pope's 'The Rape of the Lock.'

Elemi, a name given to fragrant resinous extracts obtained chiefly from trees of the order *Burseraceae*. The hard elemi, most abundant in the West Indies, is obtained from species of *Bursera*, and is either yellowish or greenish, sometimes opaque and sometimes translucent, has a fatty lustre, is easily pulverized, and very fusible. It is heavier than water, in which it is insoluble, although it is readily dissolved in either turpentine or alcohol. African elemi is an extract of *Boswellia freereana* or *Santiriopsis balsamifera*; Manila elemi a product of *Canarium commune*; and the Mauritius variety is obtained from *Canarium paniculatum*. A large part of the elemi of commerce is produced from trees of different genera of the same family growing in tropical America. Elemi is a regular constituent of spirit varnishes, and the Manila kind is used in plasters and ointments. In Eastern countries it is also used as incense. Its active principle is a volatile oil obtained by distillation.

Elephant, the largest of living land animals, the two species of which constitute the family *Elephantidae*, of the sub-order *Proboscidea*. The better-known species (*Elephas asiaticus*) is native to the jungles of India; while the other species (*E. africanus*) is found in the forests of Africa.

The elephant is a huge ungainly creature with an enormously heavy body, mounted on four short, columnar legs, the hinder ones bending like knees when he lies down, as he doubles them behind, and not under him; his tail is long and tapered, ending in a bunch of coarse hair; otherwise the wrinkled bluish-gray hide is quite hairless. His head is large, with big pendulous ears, small eyes, and a nose, prolonged into a proboscis or "trunk," which reaches quite to the ground when he stands erect. The average male elephant is 8 or 10 feet high, and weighs 5 tons or more. The incisors of his upper jaw are prolonged into tusks, which are, however, less useful to him, as weapons, than is his trunk. This organ enables the animal to pick up things from the ground, and to reach fruits or leaves many feet above his head, and it also conveys water to the mouth. Indeed, so great is the tactile sense of this singularly flexible proboscis that it has been likened to a hand. It is also its owner's chief weapon of offense and defense; for with it he can catch and crush a man with ease, or hurl aside the tiger. The age which this huge creature attains is proportionate to its size; for captive specimens have been known to live a hundred years, and scientists believe that, in a wild state, it may live many years longer.

The Indian elephant (*Elephas asiaticus*) differs from the African in having a longer head with concave forehead and smaller eyes and ears; in this species, also, the hind feet are often five-toed, whereas in the African they are never more than four-toed. Though the two species present some differences as to dentition, the special peculiarity in the structure of the molars is common to both. These teeth are of great size, and are formed of vertical plates of dental bone, separately covered with enamel, and welded together by a bony "cement," so that each tooth looks like a number of teeth, cemented together. In both species, also, there are no canine teeth, and no incisors in the lower jaw; while the incisors of the upper jaw are developed into tusks, often weighing 150 to 200 pounds each. These tusks furnish the ivory (q.v.) which is so much esteemed for ornamental purposes.

The Indian elephant has been for thousands of years the servant of man. From the earliest ages he has borne the Oriental warrior into battle, has hauled his stores and ammunition, and has even been taught to wield weapons. In peace he has piled logs and huge blocks of stone as unremittingly as a derrick, and has been the main feature in the processions of the native princes. In these last and always spectacular functions, the elephant's anklets, saddle-cloth, and trappings are often encrusted with gold and jewels; and the prince who sits in the canopied howdah on his back, is not more gorgeously attired than his elephant. In this connection, also, the albinos of the elephant are prized far more highly than the ordinary sort; in Siam, indeed, the white elephant is royal and venerated. The catching of these elephants singly, or in herds, is by no means an easy task. In former years they were caught in pitfalls, but this practice has been abandoned, because the creatures were frequently injured. Modern methods are varied. Sometimes male elephants are decoyed by tame females trained for that purpose, until they are in close proximity to the hunters. These entangle their uncon-

ELEPHANT — ELEPHANT-APPLE

scious victim's legs in stout ropes, and when, eventually, he finds himself trapped, he fights until exhausted. When, however, herds are hunted, they are driven by an ever narrowing circle of hunters toward the mouth of a strongly built stockade, or "keddah." When, after many days, surrounded and enclosed by their pursuers, they rush into the stockade, the great gate is shut upon them. They are then tamed by a variety of methods, which differ, as the stockades do, according to locality. Once caught, the elephant is easily trained, a few months being, usually, sufficient to teach him all he needs to know. Methods of training vary in detail; but, after the first severe lessons, the trainer usually finds gentleness effective. The driver or mahout sits upon the elephant's neck and manages him by words and by the use of a small iron-pointed stick. Once tamed, elephants, except in cases where they become "bad," and have to be shot like mad dogs, are so gentle that children may be trusted to play with them.

Besides the differences between the two species, already noted, the African elephant is not as amenable to domestication and confinement as the Asiatic, and is the chief source of the world's supply of ivory. Indeed, the African elephant generally succumbs to disease and dies in confinement, while the only change noted in the Asiatic under the same circumstances, is that the species generally does not breed in captivity. The African elephant is peculiar in that the great tusks, twice as large as those of the Asiatic species, are present in both male and female, while in the Asiatic species they are found only in the male. Because of the demand for these, the African natives have made war upon the female as well as the male, and this leads naturally to a diminution of the species, as the number of tusks shipped has increased rather than decreased each year. The African elephant is now never used as a beast of burden, though in ancient Egypt he may have been so utilized.

Elephants generally live in large herds, each herd led, and apparently governed, by a leader, usually the largest of the party. So marked a family resemblance exists between members of the same herd that, in India — where they are classed as "high caste" and "low caste" — different herds are easily distinguishable. The African elephants live in mountainous regions, the Asiatic ones in deep forests, whence they can issue to play in and drink of the waters in which they find so much enjoyment. Here, too, their trunks are serviceable. They are used to squirt water over the creatures' backs, or to spout it, playfully at their neighbors. Elephants also caress each other by means of their trunks.

The anecdotes illustrating the docility, affection, sagacity, irritability, capriciousness, and revengeful spirit of the elephant, are innumerable, and may be found in various well-known books on natural history. The natural enemies of the elephant, beside man, are the tiger and the rhinoceros, and the nasal horn of the latter often proves a more formidable weapon than the trunk and tusks of the elephant, and the sight of even a dead tiger is said to be enough to excite most elephants into a transport of fury.

Fossil Elephants.—Mammoths, whose remains have been dug up, frozen or fossilized. The two living species of elephant are the last

survivors of a group which formerly spread over all the great continents, and inhabited temperate and arctic as well as tropical regions. Various extinct species of the elephant, commonly called mammoths (q.v.), have been found in every country of Europe, in Asia, and Africa, and in the New World, from Alaska to Argentina. In Siberia their remains are so abundant that fossil ivory forms a considerable article of commerce. The mastodons (q.v.) distinguished from the true elephants by less specialized grinding teeth, had an almost equally extensive range, but inhabited more especially the temperate regions during the Pliocene and Pleistocene epochs. Primitive mastodons lived in Europe and North America during the Miocene Epoch; they were of smaller size than the later mastodons, and had two small tusks in both upper and lower jaws; these tusks have a band of enamel on the outer surface, and in the oldest species the upper tusks curve downward and the lower ones upward in a manner that indicates their origin from chisel-shaped incisors like those of rodents. The trunk in these primitive mastodons appears to have been much shorter than in the present elephant, and in every respect they were much less specialized. From this stage up to the present elephant a complete evolutionary series can be traced, but the earlier stages in the evolution of the *Proboscidea* are not known. It appears certain that they did not originate either in North America or Europe, but migrated to those regions during the Miocene Epoch, from some other continent. Prof. Osborn has considered them as probably of African origin; while Prof. Ameghino has recently announced his discovery of the early stages of their evolution in Argentina. The *dinotherium* (q.v.) of Europe was a side branch of the *Proboscidea*, contemporary with the primitive mastodons, and more primitive in the grinding teeth, but with more specialized tusks, the upper tusks being lost and the lower ones enlarged, while the reverse is the case in the mastodons and elephants.

Elephant, Order of the, an ancient Danish order of chivalry. It is said to have been instituted about the end of the 12th century by Canute VI. to perpetuate the memory of a Danish crusader who had killed an elephant in the Holy Land. It was renewed by Christian I. in 1462, and placed on its present footing in 1693 by Christian V. It is the highest of the Danish orders. The number of members, not counting those of the royal family, is restricted to 30. Foreign sovereigns are exempted from these restrictions. The fête of the order is held on 1 January, when the knights meet in the chapel of the order in the castle of Fredericksburg, taking rank by seniority upon seats over which are suspended their arms and devices. The insignia of the order are an enameled white elephant, with a negro mahout, bearing on a blue housing, bordered with gold and crossed with white, a sculptured tower. On state occasions the elephant is worn attached to a chain composed of elephants and castles of gold, with a letter D in gold to represent *Dania* (Denmark). The device of the order is *Magni animi pretium*.

Elephant-apple, a large and handsome East-Indian tree (*Feronia elephantum*). It be-

ELEPHANT BEETLE.

ELEPHANT BEETLE—ELEPHANT'S-FOOT

longs to the orange family, and produces a large gray-colored fruit with a very hard rind.

Elephant Beetle, one of the great cetonian beetles of the genus *Megasoma* of Central and South America; specifically *M. elephas*. It reaches a length of three to four inches, and is black, delicately pitted. A related species (*M. thebesites*) occurs in California.

Elephant Fish (*Callorhynchus antarcticus*), a fish of the sub-class *Chimæroidea* or *Holocephali* (q.v.), found in southern seas, where it is the sole representative of its kind. The name alludes to the prominent projecting appendage of the snout. The young remain until an advanced stage of development within the remarkable horny egg-cases, where they are supplied by a current of water which enters and leaves by two pairs of orifices. The fish attains a considerable size and is sometimes eaten in New Zealand.

Elephant River, a river of Cape Colony, running into the Atlantic after a course of 140 miles.

Elephant Seal, the largest of the eared seals (*Macrorhinus leoninus*), usually over 20 feet long, with a circumference of 12 feet around the thickest part of the chest. The female is much smaller than the male. In color, this seal is grayish; its body is covered with short hair, growing in patches, which gives a spotted look to the animal. The head is proportionately large, with prominent eyes and thick eyebrows; the whiskers are long; and the canine teeth are so large as to form heavy tusks. The nose of the males is prolonged into a proboscis about a foot long, which, seemingly useless, hangs loosely over the face. When this is dilated, it gives a new character to the creature's voice. This species has been almost exterminated, owing to the demand for its oil, though less than a century ago it was plentiful in the southern hemisphere. The skin is not valued for its fur and the flesh is not edible. The herds migrate southward in summer and northward in winter to avoid the extremes of temperature.

Elephant-shrew, the typical species *Macroscelides*, of the family *Macroscelididae*, belonging to the order of insect-eating mammals. The body, in general appearance and size, resembles that of the common rat. The popular name alludes to its peculiar, elongated nose, which looks like an elephant's trunk. The hind legs, which are long, and out of all proportion to the length of the fore legs, fit the animal for jumping, giving it the additional name of jumping-shrew. This insect-eater is confined to Africa. It moves by jumps, lives on the sandy plains, makes burrows in the sand, and finds its prey among the grass and bushes.

Elephanta, ɛl-ě-făn'tă, or **Elephant Isle**, called by the natives *Gharipur*, a small island in the Bay of Bombay, seven miles northeast of Bombay. It consists of two long hills and an intervening valley. It is celebrated for a cave temple 130 feet long, 123 broad, and 18 high, supported by pillars cut out in the rock. Many of these were cut down by the Portuguese. There are eight pillars or pilasters and in the centre is a gigantic trimurti or three-formed god—Brahma the creator in the middle, with Vishnu the preserver on one side, and Siva the

destroyer on the other. There are other pieces of sculpture, and also several other rock-caves. The date of these constructions is not known. A large stone elephant, which once stood near the landing place, gave name to the island.

Elephantiasis, properly speaking, a peculiar and rare disease, sporadic or endemic in warm climates, and characterized by a chronic thickening of the skin and the underlying tissues, usually limited to a definite area, and subsequent to an impairment of the lymphatic circulation. The disease is of great antiquity, and exhibits a great variety of forms, by reason of which it has received a large number of names, medical as well as popular. The term is now applied by the best dermatologists to one disease, and not to several as heretofore. Elephantiasis exists in an endemic form in Africa, India, the Indian Archipelago, the West Indies, and South America. The recent territorial acquisitions of the United States bring this disease in their train. The endemic form of the disease commences rapidly. There is pain, heat, swelling, and temperature. The lymphatics and blood-vessels soon become involved, and the part affected seems to be attacked by erysipelas. In a few days the acute symptoms may subside. A recurrence of the attack leaves the arm, or leg, or scalp, or face, or genitals somewhat thicker, and repeated attacks may result in enormous deformities of the affected parts. In the most characteristic cases of the tropical countries the disease seems to be due to a blood parasite, the *Filaria sanguinis hominis*. This worm gets into the blood, at times through the agencies of mosquito bites, and blocks up the lymphatic channels. In other cases the disease is regarded as a form of chronic erysipelas. In a few instances it is congenital. The treatment will depend largely on the type of the disease. Rest in bed, elevation of the limb, quinine for the *Filaria*, and prompt medical attendance are the essentials. See *FILARIA*; *PARASITES*.

Elephantine, ɛl-ě-făn-ti-ně (Arabic, *Djeziret-es-Zaher*, "isle of flowers"), a small island in the Nile, opposite Assouan (Syene), remarkable for the ruins with which it is covered. The island is almost covered with ruins piled up on each other—Egyptian, Roman, Saracen, and Arabic. At the beginning of the present century there were the remains of two temples in Elephantine, one a very interesting one built by Amunoph III. They were destroyed in 1822 by the governor of Assouan in order to obtain stone for building a palace. The greater part of the Nilometer, mentioned by Strabo, which stood at the upper end of the island, shared the same fate. The quay built of blocks taken mostly from older monuments, is from Roman times. Many fragments of pottery with inscriptions in Greek have been found, some of these being receipts for taxes.

Elephant's-ear, a name frequently given to plants of the genus *Begonia* (q.v.). It is applied specifically to a Hawaiian plant commonly known as *Caladium esculentum*.

Elephant's-foot, or **Hottentot's-bread** (*Tamus* or *Testudinaria elephantipes*), a plant of the yam order (*Dioscoreaceae*), of which the rootstock forms a large fleshy mass, curiously truncate, or somewhat resembling an elephant's foot, and covered with a soft, corky, rough and

ELEUSINE—ELEVATORS

cracked bark, recalling the shell of a tortoise, whence its other name. From this springs annually a climbing stem, which bears the leaves and flowers, these being small and yellow. The starchy rootstock is used as food by the Hottentots. The plant is not unfrequent in hot-houses. The American plants known as elephant's-foot belong to the genus *Elephantopus* of the *Compositæ*. The genus comprises 14 species, natives of tropical or warm regions. Three are found in the United States, mostly to the south of Delaware. The best known is the Carolina elephant's-foot (*E. carolinianus*). This is an erect hairy herb, with thin oval leaves and bracted heads of blue or purple flowers in branching corymbs. It grows as far north as southern New Jersey, and west to Kansas, and is abundant in all the region to the south. Another species is known in the Southern States as tobacco-weed and devil's grandmother.

Eleusine, ĕl-ŭ-sī'nē, a genus of grasses comprising six species, all natives of the Old World. The genus is represented in America by *E. indica*, the crab-grass or yard-grass, which is found in waste places all over North America except in the extreme north, naturalized from Asia. In its native places it is an important article of commerce. *E. corocana*, called in the west of India natchnee, nagia, ragie, and mand, forms a principal article of diet among the hill people of the western Ghauts in India. It is cultivated also in Japan. *E. stricta* is also used for food.

Eleusinian Mysteries, festivals held annually at Eleusis, a town of Attica, in honor of the goddess Demeter, or Ceres, the patroness of agriculture, and procreative power of nature. The usual opinion is that they were begun by Eumolpus, the first hierophant, 1376 B.C. Great secrecy was observed in the celebration of the festivals, consisting of the greater and lesser mysteries. The greater mysteries were celebrated toward the end of September and 1 October, lasting nine days. The lesser mysteries took place at Agræ on the Ilissus during spring time. See Walter Pater, 'Greek Studies; Demeter and Proserpina'; Jacob Cooper, 'The Eleusinian Mysteries.' It was a capital offense to reveal any of the rites. They existed about 18 centuries, and ceased during the invasion of Alaric I., in 396.

Eleusis, ĕl-lŭ'sis, a ruined village of Attica, but in ancient times a city of Greece, 12 miles from Athens. It was celebrated as the chief seat of the worship of Ceres (Greek Demeter), whose temple here was the largest sacred edifice in Greece. The Greek government began here an elaborate system of excavations in the year 1882, with the result that many remarkable ruins have been discovered. A little village, poor and mean looking, called Leusina, stands on the site of what was once powerful Eleusis. Consult: Diehl, 'Excursions in Greece.'

Eleuthera, ĕl-lŭ'thĕ-rā, one of the largest of the Bahama Islands. It is like most of the islands of the group, long and narrow, its length being about 70 miles; area, 234 square miles. Its chief production is pineapples. Its chief town is Governor's Harbor. Pop. 7,200.

Eleutheria, ĕl-ŭ-thĕ'rī-ā (Gr. *ελευθερία*, freedom), among the ancient Greeks, a festival commemorative of deliverance from the armies

of Xerxes. It was instituted after the battle of Plataea (479 B.C.), and celebrated annually at that place in the month Maimacterion, nearly corresponding to our September. At the dawn of day a procession marched through the town, at the head of which trumpeters blew the signal for battle. At midday a chariot was driven toward the altar crowned with myrtle and various garlands, and leading behind it a black bull. In front of the altar the archon of Plataea immolated the bull to Jupiter and Mercury, eulogized the heroes who had fallen at Plataea, and sprinkled the ground with wine. Every fifth year these solemnities were attended by contests, chaplets being the reward of the victors.

Eleutheria Bark, a name for cascarilla bark. See **CASCARILLA**.

Elevation, in the liturgy of the Roman Catholic Church, the act of lifting up by the celebrating priest and presenting to the sight of the faithful, the Host and the Chalice immediately after the consecration; this is the Elevation by eminence. There is both in the Latin and in the Greek Church liturgies another Elevation shortly before the communion. Prior to the promulgation and condemnation of the teaching of Berengarius in the 11th century, the Elevation after consecration appears to have had no place in the Latin liturgy; but from the beginning of the 12th century, when this custom was introduced, it spread rapidly and became universal and obligatory. It was the Church's way of confessing her faith in the truth of transubstantiation attacked by Berengarius. In the Latin Church in the 12th century began, and in the next century became universal, the custom of ringing a small bell at the moment of the Elevation, as is the present usage. But the ringing of the great bells in the church steeples and towers at the Elevation, which was pretty general in the 13th century, is now not common.

Elevation, in astronomy and geography, means generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian. In architecture, a geometrical delineation of the front or any face of a building in which all the parts are drawn according to scale and not shown as they would appear in perspective. It is one of the three designs necessary in outlining any work of architecture, the other two being the plan and the section.

Elevators. The modern elevator is a direct evolution from the machine which Elisha G. Otis exhibited in 1853 at the World's Fair in the Crystal Palace, New York. Hoists of various kinds had been built before that time, but this was the first elevator wherein provision was made for stopping the fall of the car in the contingency of the breaking of the hoisting cables. During the next five years, a number of machines were built similar to that exhibited, all being driven by belts from line shafting. In 1859 the same inventor introduced an

ELEVATORS.

For explanation, see article.

ELEVATORS.

For explanation, see article.

ELEVATORS

independent reversible engine directly connected to the hoisting machinery, and from that date the era of the elevator as a separate institution of the age began. In 1871 the hydraulic elevator was introduced, and thereafter was developed side by side with the steam machine. Finally in 1888, the electric elevator engine was introduced. There are, therefore, four general classes of elevators in use—hydraulic, electric, steam, and belt-driven. The great varieties of conditions encountered in elevator installation and operation has resulted in the development of a number of modifications of each of the four general types.

The type of elevator which is installed in greater numbers than any other is the vertical cylinder hydraulic machine. In this type, a cylinder of a diameter of, say from 8 to 24 inches (according to the water pressure and the load to be lifted), is placed in a vertical position in the elevator shaft or in any other convenient location. Within this cylinder works a piston. Attached to the upper end of the piston rods are the sheaves over which pass the hoisting cables. The length of the cylinder will, of course, depend upon the car travel and on the gearing. (See Fig. 1.) The car here shown is geared 4 to 1, although gears of 6 to 1 and 8 to 1 are quite common. For the ascent of the car, water under pressure admitted above the piston. For the descent of the car the pressure is shut off and the car descends by its unbalanced weight, the water above the piston flowing to the lower part of the cylinder through the pipe at the side known as the circulating pipe. The car is stopped at any desired point by closing a valve which both shuts off the water under pressure and closes up the path through the circulating pipe. Near the top of the circulating pipe is a simple device which limits to a predetermined maximum speed the rate at which water can flow into and out of the cylinder and therefore there is no possibility of the car moving at greater than the maximum speed in either direction.

The desired water pressure is generally obtained by suitable pumps which deliver through a pressure tank which takes up the pump pulsations. The method of controlling the valve from the car may be traced in the illustration. It will be seen that the hydraulic elevator engine is single-acting only—in fact, all styles of hydraulic machines possess this same characteristic, the car descending by its unbalanced weight (except in the pulling plunger type later to be described). It is customary with hydraulic elevators to partially counterbalance the weight of the car, leaving uncounterbalanced only sufficient weight to enable the car to descend at a proper speed.

Continuing the discussion of hydraulic elevators—in certain situations it is desirable to place all of the elevator machinery in the basement, and in such instances the cylinder is placed in a horizontal position. The horizontal cylinder hydraulic engine may be of either the "pushing" pattern wherein the car is raised during the outward stroke of the piston or the "pulling" pattern wherein the work is performed while the piston is being forced inward.

In the design of the modern city building it is highly desirable that as little space as possible be lost for rental purposes and the elevator builders have responded to this requirement (which is continually becoming more urgent) by designing a high pressure machine which is much more compact than any other type of hydraulic elevator. By using a high pressure—700 to 800 pounds per square inch—the size of the entire apparatus including the hydraulic system and pipes can be greatly reduced. The cylinder is suspended in an inverted position so that the plunger, which works therein, on being forced downward causes the car to ascend, as may readily be seen by inspection of the illustration. The high pressure hydraulic engine is also made with horizontal cylinder designed to be placed in the basement. In fact, the horizontal high pressure type is the latest development in elevator engineering. To maintain the pressure necessary for the operation of this system an accumulator of the weighted type is substituted for the pressure tank used in the low pressure systems. The motion of the accumulator governs the pumps, controlling the delivery of water in accordance with the requirements of the service. This is accomplished either by mechanical connections to the steam valves, or by a series of switches when the pumps are driven by electric motors.

The pulling plunger type of hydraulic elevator differs from any other in that when lifting the load it does not consume water, but discharges it from the cylinder. In this elevator the weight of the plunger itself, which is of solid steel, lifts the load, the plunger descending into the cylinder as the car rises in the hatchway. For the descent of the car, the water is admitted at the required pressure under the plunger and, assisted by the weight of the car, raises the plunger and the car descends. The remaining class of hydraulic elevators is the plunger or direct lift type. In this type, a cylinder of a length equal to the car travel is set vertically in the ground. In this cylinder works a plunger of the same length, carrying the car on its top. Water is admitted to and discharged from the cylinder at the top, the annular space around the plunger affording ample passageway for the water. As usual, water under pressure is admitted to the cylinder for the ascent of the car and for the descent is allowed to run out.

Electric Elevators.—The construction of a modern electric elevator engine may be described as follows: A motor is connected to suitable winding machinery by means of a worm shaft (a continuation of the armature shaft) engaging with one or two worm wheels, the latter being rigidly connected to the winding drum (in the case of elevators for ordinary freight or passenger service) or connected by means of suitable gearing (for hoists of very large capacities). On the armature shaft and worm shaft a brake wheel is mounted. A brake band is normally held tightly against this wheel by a heavy spring, thus locking the elevator engine. On starting the motor, current is also admitted to a solenoid, the action of which removes the tension from the brake band, allowing a free movement of the motor shaft. On the stop-

ELF — ELF-ARROWS

ping of the current, the brake is instantly applied by the spring.

Various electric controlling devices have been used with electric elevators. The one most generally used as being the most perfect, operates on the following principle:

On starting the car, the attendant therein moves the lever or switch (as the case may be). This movement admits starting current only to the motor, and thereafter the operations are entirely automatic. As the motor accelerates, the starting resistance is cut out step by step automatically by a series of magnets and thus the current is absolutely prevented from increasing above the amount for which the motor is designed, and a gentle and uniform acceleration is secured. Fig. 2 shows a standard magnet controller for passenger service. In machines of the smaller capacities, there is but a single worm wheel and the end thrust is taken up by ball bearings at the extremity of the worm shaft. In the larger machines, there are two worm wheels, the thrusts of the two compensating each other. Fig. 3 shows a standard electric elevator engine for high-speed passenger service. By proper proportioning of the capacity of the motor and by using a suitable train of gears electric engines may be designed for special, heavy service, and numerous incline railways in various parts of the country for handling teams, passenger cars, and hoists for heavy mine and blast-furnace work, etc., are operated by electric engines working on a principle similar to that above outlined.

The electric elevator with push-button control, is a type designed particularly for private residences. (See Fig. 4.) No attendant is required and the elevator is always ready for service. A passenger desiring to use the elevator presses a button placed near the elevator shaft, and the car, if not in use, immediately travels to that floor and stops automatically. When the car has come to rest at that floor, the door can be opened.

After having entered the car and closed the door, the passenger presses a button corresponding to the floor to which he wishes to travel and the car at once proceeds thereto and the door at that floor can then be opened. After the passenger has left the car, and closed the door, the car may again be summoned from any of the floors as before. In addition to its wide-spread use in private residences, this type of elevator is frequently used in hospitals and apartment houses where it is desired to dispense with an operator.

In the duplex motor electric elevator (Fig. 5) the drum is dispensed with and a sheave is placed on the end of each of the two armature shafts and endless cables pass round these sheaves and are connected to the car and also to the counter-weights by running sheaves. The motors run in opposite directions, and as one or the other of the motors accelerates, the car moves up or down in the hatch-way, its speed being proportional to the difference of speed of the two motors. When both motors are running at the same rate of speed the car is stationary. This type of electric elevator is particularly suitable for the service in which long car travel, fast car speed and rapid reversals are essential features.

Steam machines may be dismissed with simply a reference, as machines of this class are seldom installed now except for freight purposes, having been replaced for passenger service by the newer hydraulic and electric types. In Fig. 6 is shown a new type of steam hoist designed particularly for use on board ships. A marked economy in loading and unloading has resulted in those vessels where these hoists have been installed. The particular hoist illustrated herewith has a capacity of 4,000 pounds net load at a speed of 100 feet per minute, the size of the platform being 7 by 10 feet. Hoists of this character, however, can be made any desired power. The engine can be fitted with an automatic device whereby, at the beginning of a loading operation, the engine is automatically brought to a stop when the platform reaches the lowest deck. When this deck is completely loaded, the device is readjusted to stop the engine automatically, when the platform is lowered to the next deck, and so on. When all the decks are completely loaded, the platform is lowered to the bottom of the hatchway. The main winding drums are then thrown out of gear and the auxiliary hoist, which can be seen in the illustration, becomes operative. The hatchway may then be filled with cargo by means of this auxiliary hoist. In unloading, these operations are, of course, reversed. Belt elevators consist of winding machinery geared to pulleys whereby they may be driven from a counter-shaft. Machines of this type are comparatively inexpensive and are used extensively for freight purposes in factories.

While the factor of safety in the standard make of elevators is such that accidents very rarely occur and practically never where proper attention is paid to the elevator machinery, still all elevators are equipped with standard safety devices. The safety devices consist primarily of a governor of the centrifugal type which is connected to the car entirely independently of the hoisting cables. In the contingency of the car, for any reason, exceeding the speed for which the governor has been set, the governor rope which normally runs freely is tightly clasped and the drum under the car is rotated and the powerful grips such as may be seen in the illustration (Fig. 7) come into play, bringing the car to a safe and easy stop.

THOMAS E. BROWN,
Chief Engineer Otis Elevator Co.

Elf, a little sprite of human form supposed to inhabit wild and desolate places, and to exercise a mysterious power over man; a fairy, a goblin.

Elf-arrows, Elf-bolts, Elf-shot, are the names given to implements of stone, especially flint, of various sizes and forms, which are found abundantly in many countries, and are the remains of arrow-heads, darts, and other rude ancient weapons from the Palæolithic Period. They belong to the same class of ancient implements as are described in our article CELTS (stone hatchets). These rude and ancient implements are objects of some extraordinary superstitions. The names given above are, of

ELGAR—ELGIN MARBLES

course, of popular and comparatively modern origin, and imply that those who gave them were completely ignorant of the real origin and use of those weapons. These names are found independently among the peasantry in Scotland, England, and Ireland, and the superstitions associated with them are much more widely spread. According to the popular belief the stones are of supernatural origin, and various virtues are attributed to them. They are worn as charms, and used as a protection against lightning; but they are chiefly suspected of mischievous consequences. A cavern has been pointed out where the archfiend carries on the manufacture with the help of attendant imps, who rough-hew them while he finishes the work. Similar superstitions prevail in Italy, Africa, and Turkey. Consult: Evans, 'Ancient Stone Implements of Great Britain.'

Elgar, Edward William, English composer: b. Broadheath, Worcestershire. Among his compositions are: 'The Black Knight' (1892); 'Choral Suite: from the Bavarian Highlands' (1895); 'Lux Christi,' produced at the Worcester Festival (1896); 'Te Deum,' sung at the Hereford Festival (1897); 'Caractacus,' produced at the Leeds Festival (1898); 'Sea Pictures,' for the Norwich Festival (1899); 'Dream of Gerontius,' for the Birmingham Festival (1900); 'Coronation Ode' (1902).

Elgin, El'gin, James Bruce, 8TH EARL OF, and 12TH EARL OF KINCARDINE, English statesman: b. London 20 July 1811; d. Dhurmsala, North India, 20 Nov. 1863. He was educated at Eton and Oxford; in 1841 entered Parliament as member for Southampton, and in the same year succeeded to the earldom. In 1842 he was appointed governor of Jamaica. His rule in Jamaica was so successful that in 1846 he was appointed governor-general of Canada, and there he succeeded by a conciliatory policy in allaying the discontent which had broken out and for some time continued. In 1849 he was raised to the British peerage as Baron Elgin; was sent in 1857 as special ambassador to China, where in the following year he succeeded in concluding the Treaty of Tientsin. He also concluded a treaty with Japan. In 1860, the Chinese emperor having manifested unfriendliness, Lord Elgin was sent to enforce the treaty, which he did by entering Peking in state and destroying the imperial summer palace. Immediately thereafter, in 1861, he was appointed governor-general of India. He maintained internal peace, and exerted himself unceasingly for the development of the country.

Elgin, Thomas Bruce. See BRUCE, THOMAS; ELGIN MARBLES.

Elgin, Ill., a city of Kane County, 36 miles west by north of Chicago. Two railroads supply adequate shipping facilities, the Chicago, M. & St. P., and the Chicago & N. It is also the terminus of the Aurora, Elgin & Chicago Railway, which is a third-rail electric line between these cities, and is the finest road of its kind in existence.

Industries, etc.—Two products make Elgin famous—butter and watches. The dairy interests have probably had more to do with the development of the community than any other factor. Early in its history, The Borden Condensed Milk Company located a large plant

here and since that time has established many more in the immediate vicinity. The current quotations of the Elgin Board of Trade fix the market price of high grade butter throughout the entire country. The other industry to which Elgin largely owes its growth and prosperity is the making of fine watch-movements. The watch factory was started in the spring of 1864, and has been a success from the beginning. There are many other industries in Elgin, all of which are prosperous concerns. Two watch-case factories and as many shirt factories distribute their products throughout the country. Besides these, there are shoe, pipe-organ, automobile, coffin-fixtures, canning, malted-milk, and rug factories. Two large publishing houses are located here, and there are several machine shops and foundries.

Public Institutions, Buildings, etc.—Elgin is sometimes called the "City of Churches." Nearly all denominations are represented and the various houses of worship are large and handsome. The city is noted for its public school system, which is highly developed and very efficient. The buildings are handsome in architecture and a new high school is in the process of construction. The Elgin Academy of the Northwestern University is a well-known preparatory school for the latter institution, which is located at Evanston, Ill. Saint Mary's Academy is also well known throughout the State and bears a high reputation as a place of learning. The Illinois Northern Hospital for the Insane is located in Elgin. The Elgin Woman's Club has built and now operates a hundred-thousand-dollar hospital, which is famed throughout the country and State for its high standing and great efficiency. Three daily papers are published in the city, the *Daily News* leading in circulation and standing. The banks are six in number, four national and two savings. They have a combined capital of \$650,000 and are prosperous and strong financial institutions.

History, Government, etc.—Founded in the spring of 1835, Elgin has grown rapidly in size and importance until it now is the most beautiful and the second largest city in Kane County. Elgin was incorporated in 1854 and Dr. Joseph Tefft was chosen the first mayor. The water-works and sewer system and an electric lighting plant are the property of the municipality and its bonded indebtedness is small. Property is in great demand, owing to the number of Chicago people who, on account of good transportation facilities, are seeking more room and pleasanter homes within the confines of the beautiful city on the Fox. Elgin is growing fast in population and wealth and promises to become one of the best cities in the great State of Illinois.

RICHARD LOWRIE,
Of the 'News Advocate.'

Elgin Marbles, the name given to a peerless collection of antique sculptures brought from Athens to England by Thomas Bruce, 7th Earl of Elgin, in the early part of the 19th century. While ambassador at Constantinople (1799-1802) he conceived the plan of securing some portion of the ruins of ancient Athens, and to that end secured permission of the Porte to take "any stones that might appear interesting to him." At his own expense (the British government having refused any aid) he set a corps of artists to work who toiled for 10 years detaching various specimens from the

Parthenon, consisting chiefly of the colossal statues on the tympana of the pediments, the metopes and the frieze around the cella. Among the best preserved examples which this splendid effort brought forth were the tympanum representing the birth of Minerva, the 15 metopes showing in high relief the combats of the Centaurs and Lapithæ and the slabs from the cella frieze depicting in low relief the great Panathenaic procession. In addition to these Lord Elgin procured the colossal statue of Bacchus from the choragic monument of Thrasylus, one of the caryatides from the temple of Pandrosus, a portion of the frieze from the Erechtheum, and fragments of the columns of the Parthenon and Erechtheum; also numerous inscriptions, urns, etc., found in the neighborhood. When these treasures of antiquity arrived on the English shores they were received with a mixture of admiration and indignation—the latter because of supposed vandalism. It is said that Lord Byron was so outraged by the alleged depredations that when he visited the Parthenon he inscribed conspicuously: *Quod non fecerunt Gothi, hoc fecerunt Scoti*. However, as it afterward proved, had not Lord Elgin obtained these sculptures they would have been destroyed in the subsequent war of Greek independence, and especially in the last siege of Athens in 1826-7. After much hesitation and bickering as to the price, in spite, too, of their value vouched for by experts, the British Parliament purchased the marbles from Lord Elgin for £35,000, easily a third less than he had expended upon them. They are now to be seen in the British Museum as priceless examples of the highest in Greek art which matured under the glorious genius of Phidias. Many casts have been taken of these unsurpassed relics of which the city of New York possesses a set.

Eli, ʿēlī, Hebrew judge and high-priest of Israel. After a turbulent rule of 40 years, he died 1116 B.C. Failing to punish the misdoings of his sons, Phineas and Hophnai, the downfall of his house followed.

Eli Perkins. See LANDON, MELVILLE. D.

Eliā, ʿēlī-ā. See LAMB, CHARLES.

Elie de Beaumont, Jean Baptiste Armand Louis Léonce, zhōn bāptēst ār-mān loo-ē lā-ōns ā-lē dē bō-mōn, French geologist: b. Canon, France, 25 Sept. 1798; d. there 22 Sept. 1874. He was educated in the Polytechnic School; became professor at the School of Mines 1829; professor of geology in the College of France 1833; chief engineer of mines 1833; member of the Institute 1835; and perpetual secretary of the Academy of Sciences 1853. He published 'Carte géologique de France' (1843); 'Notices sur les systèmes de montagnes' (1852), etc.

Eligius, ʿ-lijj'ūs, or Eloi, ā-lwā. Saint, bishop of Noyon: b. Cadillac, near Limoges, 588; d. Noyon 1 Dec. about 660. Having in boyhood shown a decided aptitude for fine art he was placed by his parents under the direction of the master of the mint at Limoges, and there acquired skill in the goldsmith's craft. Appointed coiner to the Frankish king, Clotaire, and to his son and successor, Dagobert, he executed at their order the bas-reliefs on the tomb of St. Germanus, bishop of Paris, and other works in the precious metals which were re-

garded as the masterpieces of decorative art in that time. He was a favorite at court, which he was obliged to frequent because of his connection with the king; but he took more pleasure in relieving the needy than in the society of the worldly. He daily fed a large number of poor people, he buried the bodies of malefactors, and he ransomed captives, especially the Saxon slaves who were often sold in the markets. Both Clotaire and his son Dagobert bestowed costly presents upon Eligius, but they could not make him rich, he gave so much to the poor and to the founding of charitable institutions. At about the age of 50 he decided to abandon the world entirely and devote himself to the conversion of the pagans. Two years later he was ordained priest and in 546 was made bishop of Noyon. As bishop he gave special attention to the conversion of the Flemings and Frisians, and the greater part of Flanders was converted through his efforts. See Lebeuf, 'Histoire du diocèse de Paris'; Fleury, 'Vita S. Eligius.'

Eli'jah, Hebrew prophet. He flourished during the reigns of Ahab and Ahaziah, and until the beginning of the reign of Jehoram. He was especially employed to denounce vengeance on the kings of Israel for their apostasy from the national faith, and many miraculous circumstances are recorded of his life. He incurred the anger of Jezebel, the wife of Ahab, for slaying the prophets of Baal and of the groves at the brook Kishon, and she instigated her husband to put him to death; but Elijah fled to Horeb, where he received a divine manifestation, and afterward returning to Samaria denounced the vengeance of God against Ahab for the murder of Naboth and the usurpation of his vineyard. Elijah was at length taken up to heaven in the presence of Elisha, his successor, who saw him ascend in a chariot of fire (2 Kings ii.). This event occurred, according to Ussher, 896 B.C.

Elijah, The, an oratorio by Mendelssohn, first performed at Birmingham, England, 26 Aug. 1846. It is one of his best-known works and is more popular in England and America than any other oratorio, with the exception of Handel's 'Messiah.' The words are taken from the Old Testament.

Elimina'tion, the separation and exclusion of some particular substance from a compound, or of some particular symbol from an algebraic expression, thus simplifying the compound or expression, and rendering it capable of further analysis and use. It is a process by which, where we have a number of statements concerning several quantities, we can obtain a separate statement concerning each. Thus, in mathematics, broadly speaking, elimination is the operation which consists in getting rid of a common quantity. See 'Theory of Equations' (1901), Burnside and Panton.

Eliot, Charles William, American college president: b. Boston, Mass., 20 March 1834. He was graduated from Harvard in 1853, was tutor in mathematics there 1854-8, and assistant professor of mathematics and chemistry in the Lawrence Scientific School, Harvard, 1858-63. After spending two years in Europe investigating educational methods he was professor of analytical chemistry in the Massachusetts Institute of Technology 1865-9. In the last-named

GEORGE ELIOT

ELIOT

year he became president of Harvard University which position he still holds. He is one of the foremost writers and speakers of the day upon educational and social problems and has exerted a strong influence upon the travel of American thought. He has published 'Manual of Qualitative Chemical Analysis' (with F. H. Storer); 'Manual of Inorganic Chemistry' (with F. H. Storer); 'Five American Contributions to Civilization and Other Essays'; 'Educational Reform.'

Eliot, George (pseudonym of MARY ANN or MARIAN EVANS CROSS), English novelist: b. Arburyfarm, near Nuneaton, Warwickshire, 22 Nov. 1819; d. Chelsea, England, 22 Dec. 1880. She received her early education at Attleborough, Nuneaton, and Coventry, and sooner or later, either under the tuition of masters or by teaching herself, acquired a knowledge of Greek, Latin, French, German, and Italian; she also studied Hebrew, and for some time devoted herself to the study of music, becoming an excellent piano player. She was also a constant and omnivorous reader. Shortly after her 21st year she came into personal contact with friends who held rationalistic views in regard to religious matters, and though she had previously been attached to the doctrines of the evangelical school (she had an aunt who was a Methodist preacher), her religious views now underwent such a change as to cause a breach between her and her father which seems never to have been entirely closed up. Her first literary undertaking was the continuation of a translation of Strauss' 'Life of Jesus,' commenced by her friend Mrs. Hennell, and completed by Miss Evans in 1846. In 1849 she went abroad, returning to England next year, and in 1851 took up her abode as a boarder in the house of John Chapman, editor of the 'Westminster Review.' This connection led to her being attached to that periodical as sub-editor. Various articles in the 'Review' from 1852 onward have been attributed to her, but her principal work appears to have been the writing of the summaries of contemporary literature. It was not, however, until January 1857 that she came prominently into public notice, when the first of a series of tales entitled 'Scenes from Clerical Life' appeared in 'Blackwood's Magazine.' These tales immediately arrested attention, and obtained the praise of the editor, who was informed that he was to know the author as George Eliot. Mr. John Blackwood was as ignorant of the author's identity for a considerable time as was all the world except George H. Lewes (q.v.), and one or two others. The 'Scenes' came to an end in November 1857, and in the February following, the first chapters of 'Adam Bede' were in the publisher's hands, the whole work being completed and sent in by October. The success which attended the publication of this powerful story of English rural life was unmistakable, and public curiosity was greatly excited as to the personality of the author. The credit of authorship was openly ascribed to various persons of more or less note and was claimed by others of more or less modesty and honesty. The secret soon began to leak out. Months before her second novel, 'The Mill on the Floss,' was published (1860) it was well known, among literary circles at least, that George Eliot was none other

than Marian Evans, the Westminster reviewer. By this time was established that close association and literary fellowship with the talented philosophical writer, George H. Lewes, which terminated only with the death of the latter but a little more than two years before her own. In 1861 was published 'Silas Marner,' another story of humble country life, a painful, but powerful and interesting tale. Two years later she gave to the world 'Romola,' an historical novel of Italian life in the time of Savonarola, which is considered by a select few as her greatest intellectual achievement. This was followed by 'Felix Holt,' a story dealing with political, social, and religious peculiarities (1866); 'Middlemarch,' somewhat weak and diffuse as a story, but replete with pregnant thought and clear delineation of character (1871); and 'Daniel Deronda,' containing some striking and original sketches of Jewish life and character (1876). Previous to this she had acquired some renown as a poet through the publication of several volumes of poems, among which may be mentioned: 'The Spanish Gypsy' (1868); 'Agatha' (1869); and 'The Legend of Jubal' (1874). Her last work was a series of essays, entitled the 'Impressions of Theophrastus Such' (1879). In May 1880 she married Mr. John Cross, but died rather suddenly at Chelsea on 22 December of that year. Her 'Life, as Unfolded in Her Letters and Journals,' was published in 1885 by her husband. See also: Dowden, 'Studies in Literature' (1878); Blinde, 'George Eliot' (1883); James, 'Partial Portraits' (1888); Parkinson, 'Scenes from the George Eliot Country' (1888); Stephens, 'George Eliot' (1892); Myers, 'Essays Modern' (1883); Hutton, 'Modern Guides of English Thought' (1887).

Eliot, Jared, American Congregational clergyman: b. 7 Nov. 1685; d. 22 April 1763. He was a grandson of John Eliot, the "Apostle to the Indians," and was long pastor at Killingworth, Conn. He was an able preacher, a botanist, and a scientific and practical agriculturist, was the first to introduce the white mulberry tree into Connecticut, and discovered a process of extracting iron from ferruginous sands. He was also regarded as the first physician of his day in the colony; and such was his success in the treatment of insanity and chronic complaints, that he was sometimes sent for to Newport and Boston, and was more extensively consulted than any other physician in New England.

Eliot, Sir John, English orator and statesman: b. Port Eliot, Cornwall, 20 April 1592; d. London 27 Nov. 1632. He entered Parliament in 1614 as member for St. Germans, winning immediate reputation as an orator. As vice-admiral of Devon he was energetic in suppressing piracy. In the three parliaments of 1623, 1625, 1626, he made his way to the front of the Constitutional party, joined Hampden and the rest in refusing contributions to the forced loan, and took a prominent share in the impeachment of Buckingham and in drawing up the 'Remonstrance and Petition of Right.' He was imprisoned in the Tower in 1629, and died there three years later. During his imprisonment he wrote a work on constitutional monarchy, entitled the 'Monarchy of Man,' and

several other works, including an account of the first Parliament of Charles I. under the title 'Negotium Posteriorum'; a vindication of his public conduct, entitled 'An Apology for Socrates'; and 'De Jure Majestatis,' a treatise on government. Eliot was not a Republican, but believed in constitutional monarchy, and all through his career boldly maintained the privileges of Parliament both in its individual members and as a legislative and executive body. See 'Life' by Forster (2d ed. 1871).

Eliot, John, American colonial missionary, "the Indian Apostle": b. probably at Widdford, Hertfordshire, 1604; d. Roxbury, Mass., 21 May 1690. He was graduated at Cambridge in 1622, and, after taking orders in the Church of England, quitted his native country for conscience's sake, and landed at Boston, New England, in 1631. In 1646, after two years' study of the Indian language, he delivered a long sermon in the native dialect at Nonantum, and other meetings soon followed. He shortly after began to establish his converts in regular settlements, his work meeting with approval both in the colony and at home; in England a corporation was founded in 1649 "for the promoting and propagating the Gospel among the Indians of New England," which defrayed the expenses of the preachers and the cost of printing translations. At one time there were over a dozen townships of "praying Indians" within the bounds of Massachusetts, and many more outside these limits, with numbers estimated in 1674 at 3,600; but, although the organization survived until the death of the last native pastor in 1716, the decay of the "praying towns" was rapid after the war with King Philip (1675), in which the converts suffered equal cruelties at the hands of their countrymen and of the English. There are monuments to Eliot's memory in the Indian burying-ground at South Natick, and at Newton, near the scene of his first Indian sermon. A man of earnest piety and devotion, warm-hearted, and of a singularly attractive manner, he has left a memory that is honored among the first in the history of New England. With Thomas Weld, and Richard Mather, Eliot prepared an English metrical version of the Psalms, the 'Bay Psalm-book' (Camb. 1640), as the first book printed in New England. He was also the author, among other works, of: 'The Christian Commonwealth' (Lond. 1659), suppressed by the general court, and now extremely rare; 'The Communion of Churches' (1665), the first book privately printed in America; and of translations into the Indian tongue of Baxter's 'Call'; Bayly's 'Practice of Piety' (abridged); and Shepard's 'Sincere Convert.' But the great work of his life was the translation of the Bible into the tongue of the Indians of Massachusetts (Algonquin), of which the New Testament appeared in 1661, and the whole work, with a version of the Psalms in metre, and a page of "catechism" in 1663. The longest single word in it is "Wutappesittuk-qussunnoohwehtunkquoh," signifying "kneeling down to him," in Mark i. 40; which illustrates the jest of Cotton Mather, who said he thought the words of the language must have been growing ever since the dispersion at Babel. Only 14 complete copies of the first and second editions are known to be in existence. A scientific study

of Eliot's Indian Bible was made by J. H. Trumbull (q.v.), and his MS. published 1903 as 'Bulletin 25' by the Bureau of American Ethnology, Washington. Its title is the 'Natick Dictionary,' and it is divided into two parts, the first giving the Natick words with English definitions and the second giving the English words with Natick definitions. In other words, the volume contains two dictionaries, one Natick-English and the other English-Natick. While it is devoted to the Natick language it is practically a dictionary of all the Algonquin languages of Massachusetts, for the tribes of that part of the country spoke practically the same language, though each had its dialectic variations. Eliot's 'Indian Grammar Begun' was printed in 1666; his 'Indian Primer' in 1669. The finest collection of unique and scarce copies of Eliot's works is in the Lenox Library, New York; many of them have been reprinted. The best 'Life of Eliot' is that by Francis in Volume V. of the first series of Sparks' 'American Biography' (1836); the earliest that by Cotton Mather 1691; consult also articles in the 'Cyclopædia of American Biography' (Vol. II. 1887); and the 'Dictionary of National Biography' (Vol. XVII. 1889).

Eliot, Samuel, American educator and historian: b. Boston, Mass., 22 Dec. 1821; d. Beverly, Mass., 14 Sept. 1898. He filled the chair of history and political science in Trinity College, Hartford, Conn., 1856-64; was president of Trinity College 1860-4; and overseer of Harvard 1866-72. Among his publications are: 'The History of Liberty' (1853); 'The Liberty of Rome' (1849); 'Life and Times of Savonarola' (1856); 'Manual of United States History Between the Years 1492 and 1850' (revised ed. 1873); and 'Stories from the Arabian Nights' (1879).

Eliot, Samuel Atkins, American Unitarian minister: b. Cambridge, Mass., 24 Aug. 1862. He was graduated at Harvard College 1884; was pastor of Unity Church, Denver, 1889-93, and of the Church of the Saviour, Brooklyn, 1893-8. He was secretary of the American Unitarian Association 1898-1900, becoming its president at the latter date.

Elis, e'lis, (1) A country in the west of Peloponnesus, where Olympia was situated. It was bounded on the east by Arcadia, on the south by Messenia, and ran along the coast, watered by the river Alpheus. Elis and Achaia now form a monarchy of Greece. (2) Elis, the capital of Elis, is now called Kaloskopi. See OLYMPIA; OLYMPIC GAMES. Consult: Curtius, 'History of Greece.'

Elise, or San Antonio, Colony, Paraguay, an agricultural settlement started in 1890, situated in the department of San Lorenzo de la Frontera, on the left bank of the Paraguay River, about nine miles from Asunción. Products: tobacco, sugarcane, coffee, ramie grass, etc. See PARAGUAY.

Eli'sha, a Hebrew prophet, the disciple and successor of Elijah. Many miracles of prediction and cure, and even of raising the dead, are ascribed to him. He held the office of prophet for fully 65 years, from the reign of Ahab to that of Joash (latter half of the 9th

ELIZABETH

century B.C.). Consult: Bible, 1, 2 and 3 Kings.

Elixirs, in pharmacy, are aromatic, sweetish, spirituous preparations, containing small quantities of active medicinal drugs. They are now mostly used as vehicles, and have very little potent action save that of the alcohol which they contain. Elixir aromaticum and Elixir phosphorus are the only two elixirs sanctioned by the 1890 revision of the United States Pharmacopœia.

Elizabethgrad, ě-lē-zā-bět-grād', or **Yelisa-vetgrad**, Russia, fortified town, in the government and 130 miles northwest of Kherson, in a plain on the Ingul. It consists of the town proper, built with the greatest regularity in spacious streets, occasionally lined with trees; of four suburbs, and of the citadel, surrounded by six bastions. The military colonies of the district have their headquarters here. Pop. 61,841.

Elizabeth, the wife of Zacharias and mother of John the Baptist. An angel foretold to her husband the birth of a son to her old age; and it was also foretold by the angel Gabriel to the Virgin Mary, as an assurance of the birth of the Messiah.

Elizabeth, Saint, of Hungary, daughter of Andrew II., king of Hungary, and Gertrude, daughter of the Duke of Carinthia: b. Presburg 1207; d. Marburg 19 Nov. 1231. Early in life she displayed a dislike for things worldly, as the pomp with which she was surrounded, ambition, avarice, and vain pleasures, and began to cultivate humility, piety, and great charity. According to the custom of the times, when she was only four years old she was betrothed by her parents to Louis, the son of the landgrave of Thuringia, who was about her own age. When Elizabeth was 14 years old they were married. Her husband admired his wife's piety and approved her great charity, especially during the famine in Germany in 1225, although members of his own family severely censured her. She founded hospitals in Marburg and other places within her husband's dominion. (Louis' father died the year after the betrothal, and he was the landgrave when he married Elizabeth.)

In 1227 Louis left home with Frederick Barbarossa to engage in the war for Palestine; but before reaching the Holy Land Louis died from fever. Great misfortunes soon befell Elizabeth. She was deprived of her regency by the brother of her deceased husband, and driven out of her dominion on the plea that she wasted the treasures of the state by her charities. The inhabitants of Marburg, whose miseries she had frequently relieved, refused her any asylum, for fear of the new regent. At last she found refuge in the monastery of Kitzingen, where her aunt was abbess, and later with her uncle, bishop of Bamberg, and when the warriors who had attended her husband in the Crusade returned from the East with his body, she gathered them around her, and recounted her sufferings and the wrongs done to her three children. Steps were taken to restore to her her sovereign rights. She declined the regency, however, and would accept only the revenues which accrued to her as landgravine. The remainder of her days were devoted to almsgiving, morti-

fications, and prayer. She became a member of the Third Order of Saint Francis, and in pictures she is often represented clothed in the Franciscan habit. She was canonized by Gregory IX. four years after her death. Consult: Montalembert, 'Life of Saint Elizabeth of Hungary'; Starr, 'Patron Saints'; Butler, 'Lives of Saints'; Bonaventure, 'Sermon on St. Elizabeth'; Theodoric, and Montague of Spire. There are extant manuscripts on her life, by contemporaries, Conrad of Marburg, Siegfried of Mentz, and others.

Elizabeth, queen of England: b. Greenwich 7 Sept. 1533; d. Richmond, Surrey, 24 March 1603. She was the daughter of Henry VIII. and of Anne Boleyn. After her mother had been beheaded (1536) both she and her sister Mary were declared bastards, but finally she was placed after Prince Edward and the Lady Mary in the order of succession. Thus, while the first two marriages of King Henry were both still held to be illegal, the children of both were legitimized. Elizabeth received a classical education, as was customary with women of rank in her time, and under her tutor, Roger Ascham, is said to have attained very considerable proficiency in Latin and Greek. During her father's life, as well as in the reign of her brother, various negotiations were entered into for her marriage. The Duke of d'Angoulême and Philip of Spain, who afterward married her sister, were among the matches proposed for her; but the only affair of this kind in which she may be supposed to have been personally interested was the suit of Lord Seymour of Dudley, the Protector Somerset's brother. It is certain that even during the life of Catharine Parr, the widow of Henry VIII., whom he married, his attentions to the Lady Elizabeth were only too well encouraged. Both before this marriage and after the death of his wife he was a suitor for the hand of the princess; but his ambitious designs in this and other matters were not countenanced by the council, and ultimately cost him his life.

On the death of King Edward Elizabeth vigorously supported the title of Queen Mary against the pretensions of Lady Jane Grey, by which her own title as well as her sister's were barred. She rode to meet her sister, accompanied by 1,000 horse, and this bold proceeding was of no small service in confirming the doubtful in their allegiance; but Elizabeth gained little for herself by a policy in which it was well understood she had her own interest in view. After Wyatt's conspiracy her life was in great danger, and was probably saved only by the intercession of Philip. She was committed to the Tower, from whence she was removed to Woodstock, where she was confined with great strictness. She afterward, through Philip's intercession, obtained greater liberty; but throughout the whole reign continued an object of suspicion and surveillance. The danger she now incurred developed a trait in her character which ever after continued conspicuous, her power of dissimulation. She made every demonstration not only of conformity, but of zealous adherence to the established religion. Her conduct in this must not be judged from the point of view of rigid Protestantism, which Elizabeth never professed; but there were some at least among the

ELIZABETH

Roman Catholic ceremonies and customs to which she could not be supposed to give a sincere adherence. Nevertheless, her false zeal must have been well and ably sustained, for her conduct was not left to the report of friends, but carefully watched by spies and informers. Philip was most anxious to have her married out of the kingdom; and if the Duke of Savoy, whom he proposed, was unacceptable from his Roman Catholicism, there was Eric, son of the king of Sweden, who long after continued to press his suit; but Elizabeth refused both. She felt in herself a capacity for rule, and her sister's ill health opened up for her an early prospect of the throne, which she was unwilling to peril. Mary's reign was not without advantage to Elizabeth. It tried her councilors as well as herself, and gave her the opportunity of selecting them to advantage. Her adviser throughout the whole of it was William Cecil, afterward Lord Burleigh, who had already been a minister under Edward VI., and continued for the rest of his life to be one of the chief councilors and ablest ministers of Elizabeth, to whom he was in many respects a congenial spirit.

On 17 Nov. 1558 Mary's disastrous reign came to a close, and Elizabeth was immediately recognized queen by Parliament. On entering London she was met by the bishops, whom she permitted to kiss her hand, with the exception of Bonner, "whom she omitted for sundry severities in the time of his authority." It was now that the caution and secrecy characteristic equally of Elizabeth and Cecil, and which enabled them to do such great things, appeared in spontaneous exercise. The Roman Catholic religion was still predominant in the House of Lords, and any attempt to overthrow it suddenly might have been attended with the greatest danger. Elizabeth made no immediate change in her habits. For a full month the ceremonies of the Roman Catholic Church were retained in all their state. A solemn funeral service was held for Queen Mary in Westminster Abbey, at her interment on 13 December. The queen even intimated her accession to the Pope. She retained the greater part of her sister's council, choosing only seven new councilors, who were Protestants, it is true, but not then known as such. Like Cecil and herself, they had all conformed, and possessed the necessary qualification for Elizabethan councilors of accomplished hypocrisy. Such were her difficulties, notwithstanding her great prudence, that at her coronation only one of all the bishops, Oglethorpe of Carlisle, could be found to set the crown on her head. The obstacle, it is said, was her refusal to permit the elevation of the host. She had also before this authorized the reading of the liturgy in English. The first great object of her reign was the settlement of religion. A Parliament was immediately called, to which this work was assigned. It met on 25 January, and was dissolved 8 May, but its object was already accomplished. The nation was prepared for a return to the reformed faith, and the Parliament was at the bidding of the court. The reformation of religion in England was the work of Cranmer, and had already been accomplished in the reign of Edward VI.; the re-establishment of the ecclesiastical system of the national Church on the basis on which it has remained to the present day was the work of

Cecil and Elizabeth, and it was nearly completed in this Parliament. Elizabeth had less extreme opinions than many supporters of the new faith. She was tolerant, for instance, in regard to images, and is said to have entertained scruples as to the extent of the royal supremacy in spiritual matters; but if she did, they must have been purely speculative. They certainly vanished on the first taste of power.

If the formal establishment of the reformed religion was easily completed, the security and defense of the settlement was the main object of the policy and the chief source of all the struggles and contentions of her reign. What made the position so difficult was the intolerance by which at this period and for long after all religious sects were characterized. No sooner were the Puritans freed from the restrictive measures of Mary's reign than they began to claim predominance for their own dogmas. But it was far from the intention of the queen and the supporters of the Established Church, notwithstanding the common persecutions they had endured, to grant them even liberty of worship. Elizabeth's own determination, as expressed by herself, was that none should be allowed to turn aside either to the right hand or the left from the drawn line of prescribed duty, and in insisting upon uniformity of worship she was not singular, but was acting in the spirit of her age. This principle was not less firmly held in her reign than in her sister's; and Roman Catholics on the one hand, and Puritans on the other, restrained only by their dread and hatred of each other, were made the irreconcilable enemies of the existing order. Moreover, from the necessities of the struggle the severities of Elizabeth's reign went on increasing as time advanced. At first no one suffered death for his opinions; but eventually many were executed for this cause. The struggle against Roman Catholics was the most severe, chiefly because they were supported by foreign powers; so that while their religion was wholly prohibited, even exile was forbidden them in order to prevent their intrigues abroad. Simple non-conformity, from whatever cause, was pursued with the severest penalties. The fine imposed for non-attendance at church was £20 per month, while so strait were the lines of conformity drawn, that many more clergymen were driven out of the Church by differences about the position of altars, the wearing of caps, and such like matters, than were forced to resign by the change from Rome to Reformation. These stringent measures were, however, the rigid consequences of the false position assumed.

Elizabeth's first Parliament approached her on a subject which, next to religion, was the chief trouble of her reign, the succession to the crown; they requested her to marry. She replied in a long speech, declaring her intention to live and die a virgin. It is certain, from her conduct both before and after, that this declaration was only a convenient affectation of prudery, which at once served to flatter her vanity and to veil her real indecision. She saw too clearly for her own interest the restraints to which each particular marriage might subject her, and therefore, she shunned them all, thus leaving open the question of the succession.

On Elizabeth's accession the country was at war with France. Peace was easily concluded

ELIZABETH

1559; but the assumption by Francis and Mary of the royal arms and titles of England led to an immediate interference on the part of Elizabeth in the affairs of Scotland. She entered into a league with the Lords of the Congregation, or leaders of the Reformed party; and throughout her reign this party became distinctively an English one, and was frequently serviceable in furthering her policy. She also gave early support to the Huguenot party in France, and to the Protestants in the Netherlands, so that throughout Europe she was looked on as the head of the Protestant party. This policy roused the implacable resentment of Philip, who strove in turn to excite the Roman Catholics against her, both in her own dominions and in Scotland. After the detention of Mary queen of Scots in England, he fomented the various rebellions in her favor formed in England and Ireland, and at her death declared himself her avenger. Mary, as is well known, was imprisoned 19 years in England, whither she fled to the protection of Elizabeth. Her imprisonment was followed by a series of conspiracies, beginning with that under the earls of Northumberland and Westmoreland, and ending with the plot of Babington, which finally determined Elizabeth to make away with her captive. The execution of Queen Mary was, nevertheless, the chief political blunder of Elizabeth's reign. If the death of Mary did not raise up new enemies to Elizabeth on the continent it at least gave a just cause of scandal to those she already had. Elizabeth had for some time been engaged in a negotiation for marriage with the Duke of d'Alençon (afterward d'Anjou); and in 1580 the Duke arrived in London to pursue his suit, which had lasted nearly 10 years, in person. He was well received, but still the queen hesitated. She was now 47. The following winter the Duke paid another visit, and the marriage was all but concluded, but she finally informed him she could never marry.

The state of France, as indicated by the change of government consequent on the accession of Henry IV., who was assisted by Elizabeth, obviated any danger that might have arisen from the indignation which the execution of Queen Mary had caused in that country. Nowhere, however, was that event more meekly borne than by King James. The Scottish Solomon had thought his mother's danger a favorable opportunity for sententious observations about the strangeness of her case, and now his philosophy was nonplussed. His awe of Elizabeth and his dread of interfering with his own right of succession to England made him powerless, and he accepted an addition to his pension in full of all grievances. Philip was not to be so appeased. He had other grievances, to which the execution of Mary lent edge. The fleets of Elizabeth had galled him in the West Indies, her arms and subsidies had helped to deprive him of the Netherlands; the Armada was already in preparation. Therefore he called the queen of England a murderess, and refused to be satisfied even with the sacrifice she seemed prepared to make of her Dutch allies. The Armada sailed on 29 May 1588. Its fate is too well known to need recapitulation. The war with Spain dragged on till the close of Elizabeth's reign.

During her long rule Elizabeth showed her

judgment in nothing so much as in the councilors she trusted. But while the splendor of her government at home and abroad was sustained by such men as Burleigh, Bacon, Walsingham, Throgmorton, and Davison, who served her with a zeal which did not always spare even their own reputations, she had personal favorites of less merit who were often more brilliantly rewarded. It is sufficient to name Dudley, whom she created Earl of Leicester; and Essex, who was still more a personal favorite, though much less a courtier. The latter had some merit as a soldier; but his violent temper, ill-suited to the queen's haughty disposition, brought about his ruin. He was beheaded in 1601, and Elizabeth never forgave herself his death. Her own health soon after gave way, and she died, naming James of Scotland as her successor.

Besides its political glories, the reign of Elizabeth was the golden age of English literature. If all else could be forgotten, it would be remembered as the age of Spenser and of Shakespeare, not to mention a host of minor names. The naval achievements of Drake and the discoveries of Raleigh concurred to do it honor. Thus everything conspired to throw a halo round the name of Elizabeth, when regarded as a sovereign, and seen as she would be in her own day, especially by foreign beholders, through the drapery of state. If a minute criticism has exposed some of the weakness of the individual woman who bore this burden, it must be remembered that the process is only half fair. As a sovereign she is entitled to her surroundings, and as an absolute ruler, as to a great extent she undoubtedly was, she must have her share of praise for the good that was done in her name. It is no small merit to select good councilors and to adhere to them. Elizabeth knew how to do both; and yet she was no puppet in the hands of her advisers. Though haughty and imperious to the Commons, she knew both when and how to yield. She studied with rare sagacity the temper of the people; and high as were her notions of prerogative, she may fairly be considered the first constitutional monarch of England.

Elizabeth, empress of Austria: b. Possenhofen, Bavaria, 24 Dec. 1837; d. Geneva 10 Sept. 1898. She was the daughter of Duke Maximilian Josef of Bavaria, and married her cousin, the Emperor Franz Josef on 24 April 1854. Together they were crowned with the insignia of St. Stephen when the inauguration of the dual system was solemnized. She was greatly admired by Austrians and Hungarians alike.

ELIZABETH FARNESE — ELIZABETH CITY

While visiting Geneva, Switzerland, she was assassinated by an Italian anarchist.

Elizabeth Farnese, fär-nä'zë, queen of Spain: b. 25 Oct. 1692; d. 1766. She was a daughter of Edward II., Prince of Parma. On becoming the second wife of Philip V. she surprised those who had counseled the marriage by assuming the practical headship of the kingdom; her ambition and that of her minister, Alberoni, disturbed the whole of Europe.

Elizabeth, Madame (ELISABETH PHILIPPINE MARIE HÉLÈNE), French princess: b. Versailles 3 May 1764; d. Paris 10 May 1794. She was a sister of Louis XVI. She was the faithful friend and companion of the royal family in their flight to Varennes, and during their imprisonment was executed, on the pretense of corresponding with her other brothers, afterward Louis XVIII. and Charles X.

Elizabeth, Pauline Ottilie Luise, queen of Rumania (pseudonym "CARMEN SYLVA"): b. Neuvièd 29 Dec. 1843. She married Charles of Rumania, 15 Nov. 1869. She is well known as a writer over the signature "CARMEN SYLVA," her works including 'Sappho' (1880); 'Hammerstein' (1880); 'Stürme' (1881); 'Leidens Erdengang' ('Sorrow on Earth') (1882); 'Les péchés d'une reine' (1882); 'Pelesch Märchen' (1883); 'Le pic aux regrets' (1884); 'Es klopft' (1887); etc.

Elizabeth Petrov'na, empress of Russia: b. 29 Dec. 1709; d. 5 Jan. 1762. She was the daughter of Peter the Great and Catharine, and ascended the throne on 7 Dec. 1741, as the result of a conspiracy, in which Ivan VI., a minor, who had reigned only one year, was deposed. Elizabeth is said to have rivaled her mother in beauty, and to have surpassed her in her love of pleasure. Her reign was stained both by her unbridled licentiousness and the tyranny of her government, which was conducted by favorites. Banishment to the mines of Siberia and imprisonment in dungeons were awarded for the slightest political offenses. She was a patron of literature, and corresponded with Voltaire, to whom she supplied materials for his 'Life of Peter the Great.' She also founded the University of Moscow and the Academy of Fine Arts of St. Petersburg. Elizabeth sent an army, in 1748, to assist Maria Theresa in the war of the Succession, which contributed to bring about the Peace of Aix-la-Chapelle; and she joined in the Seven Years' war against Prussia.

Elizabeth Stuart, queen of Bohemia: b. Falkland Palace, Fifeshire, 16 Aug. 1596; d. London 13 Feb. 1662. She was a daughter of James I. of England, and was married to the Palatine Frederick at Whitehall, 14 Feb. 1613. Her husband was then at the head of the Protestant interest in Germany, and in 1619 he accepted the crown of Bohemia offered to him by the revolted Protestants of that country. This he was only able to retain for a very short period; and after his defeat by the Imperialists at the battle of Prague in 1620, he and his wife were obliged to flee, first to Breslau and Berlin, and then to The Hague. Elizabeth had 13 children, several of whom died early. Charles Louis, the eldest surviving, was reinstated in the palatinate by the Treaty of Westphalia in 1648. His daughter, Elizabeth Charlotte, was

the second wife of Philip, Duke of Orleans, brother of Louis XIV. Her descendants were excluded by their Catholicism from the crown of England, but one of them was regent of France during the minority of Louis XV.; and another, Louis Philippe, ascended the throne after the revolution of 1830. Her sons, Princes Rupert and Maurice, distinguished themselves in the civil war in England. Her daughter, Sophia, married into the house of Brunswick, became electress of Hanover, and mother of George I. Elizabeth Stuart's cause was extremely popular with the English nation, and after her husband was deprived of the crown of Bohemia she still retained among them the endearing epithet of "Queen of Hearts." She returned to England at the Restoration with her nephew, Charles II.

Elizabeth of Valois, vä-lwä, or **Isabella**, Queen of Spain: b. Fontainebleau, France, 22 Nov. 1545; d. Madrid 3 Oct. 1568. She was a daughter of Henry II., of France, and Catharine de Medici. She was destined to be the wife of the infante, Don Carlos, but his father, Philip II., being left a widower, became fascinated and married her himself. The story of a romantic relationship between Elizabeth and Don Carlos has furnished tragic subjects to Otway, Campiestron, Chénier, Schiller, and Alfieri.

Elizabeth, Cape. See CAPE ELIZABETH.

Elizabeth, N. J., city, county-seat of Union County; on Newark Bay and the Arthur Kill; and on the Pennsylvania, Lehigh Valley, Baltimore & O., Philadelphia & R., and New Jersey C. R.R.'s; 14 miles southwest of New York. A ferry across the Arthur Kill connects the city with Elizabethport. It covers a wide expanse of level land, is laid out with broad and handsome streets, running at right angles, has numerous business blocks, and is noted for the large number of handsome residences of New York business men. The chief articles manufactured are sewing-machines, oilcloth, hats, saws, mill-machinery, stoves, hardware, edge tools, harness, cordage, and combs. A large business is done in the shipment of anthracite coal. The Crescent Steel Works and shipyard, in which several naval vessels have been built, are located here. Among public institutions are, the Alexian Brothers Hospital, General Hospital, Orphan Asylum, Home for Aged Women, and Public Library. The educational institutions include the Battin and Pingry high schools, the Vail-Deane School, and a business college. The city has electric lights and street railways, many old and handsome churches, two national and several private banks, building and loan associations. Elizabeth has considerable historical interest. It was settled in 1665 as Elizabethtown, and was the capital of New Jersey from 1755 to 1757. It contains an old tavern where Washington stopped on his way to New York for his first inauguration, Gen. Winfield Scott's home, the Boudinot House, and the old Livingston Mansion. Pop. (1900) 52,130.

Elizabeth City, N. C., town, county-seat of Pasquotank County; on the Pasquotank River, and the Norfolk & S. R.R.; about 145 miles northeast of Raleigh. A State normal school is located here. The region about is adapted.

ELIZABETH ISLANDS — ELKHORN

for agriculture, lumbering, and cotton raising. The manufactures of the town are varied, including cotton, flouring-, saw- and planing-mills, ship-building, and brick yards, carriage and wagon factories. The town was founded in 1793, and now has a government consisting of a mayor and a municipal council. A naval victory was gained here by the Federals under Commodore Rowan, 10 Feb. 1862. Pop. 6,500.

Elizabeth Islands, a Massachusetts group, 16 in number, forming the town of Gosnold, in Dukes County. They are situated between Vineyard Sound and Buzzard Bay; area, 14 square miles. In 1602 the first New England settlement was made on one of these islands, Cuttyhunk, by Bartholomew Gosnold; but after a residence of a few weeks it was abandoned, and Gosnold returned to England (see GOSNOLD, BARTHOLOMEW). The islands are now favorite summer resorts. Pop. 164.

Elizabethan Architecture, a style of architecture, which began to prevail in England during the reigns of Elizabeth and James I. It was a mixture of inferior Gothic with debased Italian, often very picturesque, but without purity and unity of design. It was characterized by deeply embayed windows, galleries of great length, very tall and elaborate chimneys, strap work in the parapets and window-heads, and many dormanted details of surface-carving characteristic of the bizarre influence of the combined Renaissance forms from Germany and Holland. The names of Holbein and John of Padua are associated with this style of architecture in which they had hoped to revive classic models.

Elizabetopol, э-лэ-зä-bet-poly', or **Yelizavetpol**, Russia. (1) A government in the southern part of Russia, area, 16,721 square miles; pop. 890,563. (2) A city in the Caucasus, capital of the government of Elizabetopol. Pop. 35,129.

Elizabethtown, Ky., city, county-seat of Hardin County; on the Louisville & N., and the Illinois C. R.R.'s; about 40 miles south of Louisville. The city is the centre of the trade in asphalt for which the county is noted, and it does a large business in live stock and agricultural products. Pop. 2,000.

Elizabethtown, N. Y., village, county-seat of Essex County; on the Bouquet River, 12 miles west of Westport, the nearest railroad station. Westport is on Lake Champlain and on the Delaware & Hudson Railroad. Elizabethtown is in the Adirondacks, on a height overlooking several beautiful valleys. It is a famous summer resort, and has quite a population in July and August. Pop. (1900) 491.

Elk, or **Moose**, the largest living representative of the deer family, the genus *Alces*, in America, called the moose. It is six and one half to seven feet tall at the shoulder; weighs from 1,000 to 1,500 pounds; is grayish-brown in color with light underparts, and carries a pair of magnificently spread antlers. These are peculiar in that they grow at right-angles to the plane of the face, and are broadly palmate, in two portions, the anterior usually the larger of the two. These antlers have been known to weigh as much as 60 pounds. The elk is further distinguished by having long limbs, a short neck, long flapping ears, a long narrow head,

terminating in a broad overhanging muzzle, and small, sunken eyes. The tail is merely rudimentary. In captivity, or even in comparison with other deer, the elk is ugly and rather ungainly. Yet, seen in the forest he presents a thoroughly majestic front to the hunter, and can move as swiftly and more noiselessly than the less bulky and more graceful members of the family. See **MOOSE**.

The elk of Europe is found on the continent, and to the far north in Scandinavia, northern Russia, and northern Prussia. In America, the moose has retreated to a great extent, toward the Northwest; and it is fairly common throughout Canada and Labrador. The summer home of the elk is near fresh water, where he can feed upon the succulent herbage. In winter he retires to the fastnesses of heavily wooded timber-land, where his food consists of twigs, leafbuds, and certain species of lichens. Like the red-deer, the elk fights for possession of his consort; and fierce combats are waged in the early autumn between stags whose antlers have matured during the retirement of summer. The peculiar blood-curdling challenge, uttered by the male at this season, is reproduced through a short trumpet of rolled birch-bark by both Indian and white hunters, who thus lure the eager elk within shooting distance of their ambush. On account of the power of endurance and strength of the creature, it is frequently made symbolic; and in many localities in Canada, persons of unusual physical power are said to be "As strong as a bull-moose." It is easily domesticated and made to draw sledges.

Of fossil species, the best known is the Irish Elk, found in the Pleistocene strata, and distinguished by its enormous antlers, the tips of which are sometimes 11 feet apart, but which differ from those of living species in that the beam is flattened into a palm. To sustain their great weight, unusually large and strong limbs, and neck vertebra, were required. While found chiefly in the peat bogs of Ireland, its remains have been discovered also in Great Britain and throughout Europe in lacustrine deposits, brick clay, and ossiferous caves.

Consult: Lydekker, 'Deer of all Lands' (London 1898); Afalo, 'Sport in Europe' (London 1901); Roosevelt (and others), 'The Deer Family' (New York 1902), and general works on zoology and sport in North America.

Elkesaites. See **ELCESAITES**.

Elkhart, Ind., city, in Elkhart County, at the confluence of the St. Joseph and Elkhart Rivers, and on the Cleveland, C. C., & St. L., the Lake Shore and the Elkhart & W. R.R.'s; 101 miles east of Chicago. It is a railroad centre and shipping point for a large agricultural region. The rivers afford excellent water power. The Lake Shore railroad shops are located here and the manufacturing interests include brass, carriage, starch, bicycle, and paper factories. Elkhart is the seat of Elkhart Institute and has public schools, business colleges, and high school, daily and weekly newspapers, gas and electric lights, electric railways, waterworks and two national banks. Pop. (1900) 15,184.

Elkhorn, a river in Nebraska formed by the junction, in Madison County, of the North Fork, which has its rise in Brown County, and

the South Fork which rises in Knox County. The general course is southeast, 260 miles, when it flows into the Platte River.

Elkin, William Lewis, American astronomer: b. New Orleans 29 April 1855. He was educated at the Royal Polytechnic School in Stuttgart, Germany, and was graduated in 1880 at the University of Strasburg. He then went to the Cape of Good Hope on the invitation of Sir David Gill, English astronomer there, and took part with him in observations with the heliometer for the determination of stellar parallax, these determinations being the most accurate of the kind ever made up to that time. He became astronomer at the Yale College observatory in 1884, where he has continued his excellent work in stellar parallax.

Elkins, Stephen Benton, American politician: b. Parry County, Ohio, 26 Sept. 1841. He removed to Missouri when a child; was graduated at the University of Missouri in 1860; and admitted to the bar in 1863. During the latter year he went to New Mexico, where he was a member of the Territorial legislature in 1864-5; and the Territorial delegate in Congress in 1873-7. Subsequently he removed to West Virginia, and became interested in railroads and coal mining. In 1891-3 he was secretary of war, and in 1894 was elected to the United States Senate.

Elks, Benevolent and Protective Order of, a convivial, charitable, and benevolent organization founded by members of the theatrical profession in New York in 1868, but now admitting to membership men in other professions and occupations. The order has one grand lodge and 820 sub-lodges throughout the country. The membership in the United States (1903) numbered more than 130,000, including many prominent men. Though not a beneficial order, it is claimed that it expends more in unostentatious charity than any other organization in the world. The benefits disbursed since organization amount to \$1,250,000, with an annual average distribution at present of upward of \$150,000.

Elkton, Ky., city, county-seat of Todd County; on a branch of the Louisville & N. R.R., near the southern boundary of the State, about 45 miles north by west of Nashville, Tenn. Its trade is exclusively in farm products, including tobacco and hops. The city has a reputation as an educational centre, its chief institution being the Vanderbilt Training School, which is under the auspices of the Methodist Episcopal Church. Pop. (1900) 1,123.

Ellagic Acid, or **Bezoardic Acid**, $C_8H_6O_8$, is separated from Oriental bezoars by dissolving them in cold strong potash, away from the air, passing a current of carbolic acid, collecting the ellagate of potassium, washing and recrystallizing it, and then liberating the ellagic acid by hydrochloric acid. It is insoluble in water, but dissolves in alcohol. It is a pale yellow, tasteless, crystalline powder, decomposed on heating. With the bases it forms salts, which are not very well known: they are crystalline, and insoluble or sparingly soluble in water. The lead and barium compounds are yellow. This acid can also be obtained from gallic acid, of which it is a product of oxidation. It was from this source that it was first got by Chevreul; it was afterward identified by Wöhler with that from

bezoars. It appears to be doubtful whether it occurs ready formed in gall-nuts, or whether it is produced in the process of extraction.

El'land, England, town in the West Riding of Yorkshire, on the river Calder, three miles southeast of Halifax. It has some cloth-mills, and there are valuable stone quarries in the vicinity. Pop. 10,485.

Ellenborough, ă'l'ën-bŭr-ō, Edward Law, LORD, English lawyer: b. Great Salkeld, Cumberland, 16 Nov. 1750; d. London 13 Dec. 1818. He was educated at Cambridge, and was called to the bar in 1780. On the trial of Warren Hastings in 1785, Erskine having refused to undertake the defense, Law served as leading counsel. It required no little courage to encounter such opponents as Burke, Fox, Sheridan, and other eminent men of the time, who conducted the impeachment. Law, as is well known, obtained the victory. In 1801 he was made attorney-general, and in 1802 became lord chief justice of the king's bench, and was created baron. He adopted the title Ellenborough from a small fishing village of that name, where his ancestors had lived for a long time. In Parliament he was opposed to the emancipation of the Catholics. He held the office of chief justice for 15 years.

Ellenborough, Edward Law, 1ST EARL OF, English statesman: b. 8 Sept. 1790; d. near Cheltenham 22 Dec. 1871. He was educated at Eton and Cambridge; entered Parliament as representative of St. Michael's in 1814, and in 1818 succeeded his father as second baron, and entered the House of Lords. He was lord privy-seal in 1828, and in 1841 accepted the governor-generalship of India. He arrived in Calcutta in time to take control of the Afghan war, which was brought to a successful issue. Scinde was conquered by Sir Charles Napier, and annexed in 1843. This was followed by the conquest of Gwalior. The conduct of the governor-general, however, gave great dissatisfaction at home. His policy at first had been vacillating, and latterly too warlike, and the vanity and indiscretion of his proclamations were looked upon as seriously impugning the soundness of his judgment. He was consequently recalled by the East India Company early in 1844. Under Lord Derby's government in 1858 he held the office of president of the board of control from February to June, during which he wrote a despatch censuring the policy of Lord Canning as governor-general of India, which caused much discussion, and led him to resign his office.

Ellensburg, Wash., county-seat of Kittitas County; on the Yakima River, and on the North P. R.R., about 130 miles southeast of Seattle. The industries of the city are those that belong to a combined mining and agricultural region. One of the normal schools of Washington is situated there. Pop. (1900) 1,737.

Ellenville, N. Y., a popular summer resort in Ulster County; on the New York, O. & W., and a branch of the Erie R.R.'s; about 20 miles west of the Hudson River. It was at one time a busy agricultural centre, but now its chief industry is the quarrying of blue-stone. Pop. (1900) 2,879.

Eller, Johann Theodor, German chemist: b. Plötzkau, in Anhalt-Bernburg, 29 Nov. 1689; d. Berlin 13 Sept. 1760. In 1721 he was ap-

ELLERIANS — ELLICOTT

pointed Anhalt-Bernburg physician; in 1724, professor of anatomy in Berlin; in 1735, physician to Frederick the Great; in 1755, privy councillor and director of the physical class of the Academy of Sciences. His papers were published in the 'Memoirs of the Berlin Academy,' and among them is a long and interesting review of the opinions held respecting the elements from the earliest times down to his own day. He also published a series of curious microscopic observations upon the change of blood corpuscles by the addition of different salts, tinctures of plants, and other solutions. Eller was undoubtedly a man of great learning and abilities, but his writings do not indicate a high degree of originality.

Ellerians, a sect of fanatics which arose in 1726, and had for its founder Elias Eller, a ribbon-weaver, who was born in 1690 at Ronsdorf in Berg. He was influenced in his religious beliefs by reading the works of Jacob Böhme, and other mystical writings. The sect committed great excesses, and became very numerous. See BÖHME, JACOB.

Ellery, William, American patriot: b. Newport, R. I., 22 Dec. 1727; d. there 15 Feb. 1820. He sat in the Congress of 1776, and was one of the signers of the Declaration of Independence. From 1790 till his death, he retained the office of collector in his native place.

Ellesmere, ěl'z'mēr, Francis Egerton, EARL OF, English author: b. London 1 Jan. 1800; d. there 18 Feb. 1857. His 'The Pilgrimage and Other Poems' (1856) constitutes his most valid title to fame, though he wrote much and well on biographical, historical, and literary subjects.

Ellesmere Land, the most northern region of the continent of North America, discovered by Baffin in 1616. The western part of this region was explored and mapped by Sverdrup, Otto (q.v.) in 1899. Ellesmere Land is a high plateau, without human inhabitants; a few reindeer, musk-oxen, and wolves find sustenance there. It is separated from Greenland by Smith Sound.

Ellet, Charles, American engineer: b. Penn's Manor, Bucks County, Pa., 1 Jan. 1810; d. Cairo, Ill., 21 June 1862. He was educated at the Polytechnic School in Paris, and on his return to America held various responsible engineering posts. He built at Fairmount, Philadelphia, the first wire suspension bridge in the United States, and in 1845 declared that a bridge could be built at Niagara below the Falls adapted for railway purposes. In the Civil War he equipped nine Mississippi River steamboats as rams, and with them defeated a fleet of Confederate rams, but died of wounds on that occasion.

Ellet, Elizabeth Fries Lummis, American prose writer: b. Sodus Point, N. Y., October, 1818; d. New York 3 June 1877. She was popular in her day, and among her books are a translation of Silvio Pellico's 'Euphemia of Messina' (1834); 'Poems, Original and Selected' (1835); 'Characters of Schiller' (1842); 'Pioneer Women of the West' (1852); 'Novelettes of the Musicians' (1852); 'Queens of American Society' (1867); 'Court Circles of the Republic,' with Mrs. R. E. Mack (1869); 'The Practi-

cal Housekeeper'; 'Evenings at Woodlawn'; 'Women Artists in All Ages.'

Ellice, ěl'is, or Lagoon Islands, a group of coral islands, situated north of the Fiji and northwest of the Samoan group. They extend for 360 miles in a direction northwest to southeast, and form nine groups, the largest islands being Sophia or Rocky Island, Nukulailai or Mitchell, Ellice, Nukufetau, Vaitupu, Netherland, and Lynx. The inhabitants almost all speak a Samoan dialect, and have traditions of a migration from the Samoan islands. They have long been Christianized, and reading and writing are general. The cocoanut is widely cultivated. These islands were annexed by Great Britain in 1892. Area, 14 square miles. Pop. 2,400.

Ellichpur, ěl-ich-poor', India, town in Ellichpur district, Berar, once large and prosperous. There is a military cantonment within two miles. The town contains many interesting ruins, including a palace, several fine tombs, and an old well. Pop. 36,240.

Ellicott, Andrew, American astronomer and civil engineer: b. Bucks County, Pa., 24 Jan. 1754; d. West Point, N. Y., 28 Aug. 1820. His father founded the town of Ellicott's Mills, Maryland, where the younger days of his son Andrew were devoted to the study of the sciences and practical mechanics. The latter's scientific attainments early attracted public attention, and from the Revolution to the day of his death he was employed in the fulfilment of trusts conferred by the general or State governments. About 1785 he removed to Baltimore, and represented that city in the State legislature. In 1789 he was appointed by President Washington to survey the land lying between Pennsylvania and Lake Erie, and during that year made the first accurate measurement of the Niagara River from lake to lake, with the height of the falls and the fall of the rapids. In 1790 he was employed by the government to survey and lay out the federal metropolis. In 1792 he was made surveyor-general of the United States, and in 1795 superintended the construction of Fort Erie at Presque Isle (now Erie, Pa.), and was employed in laying out the towns of Erie, Warren, and Franklin. In 1796 he was appointed by President Washington commissioner on behalf of the United States under the treaty of San Lorenzo el Real, to determine the southern boundary separating the United States territory from the Spanish possessions. The results of this service, embracing a period of nearly five years appear in his 'Journal' (published 1803). Upon the completion of this service he was appointed by Gov. McKean of Pennsylvania, secretary of the State land office, the duties of which he performed to the year 1808, and in 1812 became professor of mathematics at West Point. In 1817, by order of the government, he proceeded to Montreal to make astronomical observations for carrying into effect some of the articles of the Treaty of Ghent.

Ellicott, Charles John, English Anglican prelate: b. Whitwell, Stamford, England, 25 April 1819. He was educated at St. John's College, Cambridge, and after being professor of divinity in King's College, London, Hulsean lecturer and professor of divinity at Cambridge, and dean of Exeter, was appointed bishop of Gloucester and Bristol in 1863. In 1897 the

diocese of Bristol was separated from that of Gloucester, Bishop Ellicott remaining at the head of the latter diocese. He was for 11 years chairman of the scholars engaged on the revision of the New Testament translation, and has published commentaries on the Old and New Testaments, as well as 'Historical Lectures on the Life of Christ'; 'Modern Unbelief' (1877); 'Some Present Dangers of the Church of England' (1878); 'Spiritual Needs in Country Parishes' (1888); 'Sacred Study' (1892-4); 'The Revised Version of Holy Scripture' (1901); etc.

Ellicott, Henry J., American sculptor: b. near Ellicott City, Md., 1848; d. Washington, D. C., 11 Feb. 1901. His best-known works include bronze statues for the 1st and 2nd Pennsylvania Volunteers on the battlefield at Gettysburg, the equestrian statues of Gen. Hancock in Washington and Gen. McClellan in Philadelphia; and memorial monuments in various parts of the United States.

Ellicott City, Md., county-seat of Howard County; on the Patapsco River; eight miles west of Baltimore. St. Charles College (R. C.) in charge of secular clergy, and Rock Hill College, in charge of Brothers of the Christian Schools, are located here. The manufactures and trade are chiefly local. Pop. 1,408.

Ellinwood, Frank Fields, American clergyman and author: b. Clinton, N. Y., 20 June 1826. He was graduated at Hamilton College in 1849; was ordained a minister in the Presbyterian Church in 1853; and became secretary of foreign missions for that denomination in 1871. His chief works are: 'The Great Conquest' (1876); 'Oriental Religions and Christianity' (1892); 'Questions and Phases of Modern Missions' (1899).

Elliot, Daniel Giraud, American zoologist: b. New York 7 March 1835. He made zoology a special study from his youth; traveled in Europe, Africa, and parts of Asia in 1856-78; subsequently in Canada, Alaska, South America, and the greater part of the United States. He afterward became curator of zoology in the Field Columbian Museum. He has published: 'The Pheasants'; 'Birds of North America'; 'The Grouse'; 'Birds of Paradise'; 'Hornbills'; etc. He has been decorated 10 times by various European governments for his researches in natural science.

Elliot, Sir Gilbert, Scottish philosopher and poet: b. Teviotdale September 1722; d. Marseilles 11 Jan. 1777. His song of 'Amynta' beginning "My sheep I neglected, I broke my sheep hook," is famous; he also wrote occasional philosophical papers.

Elliot, Henry Rutherford, American journalist: b. Woodbridge, N. J., 1849. He has published: 'The Basset Claim, a Story of Life in Washington' (1887); 'The Common Chord, a Story of the Ninth Ward' (1888); and other fictions.

Elliot, Jane, Scottish poet, sister of Sir Gilbert Elliot: b. Teviotdale, 1727; d. there 29 March 1805. She wrote 'The Flowers of the Forest' (1756), a song of Flodden Field.

Elliot, Arthur Ralph Douglas, Scottish lawyer and author: b. 17 Dec. 1846. He was educated at Edinburgh and Cambridge, was called to the bar in 1880, and was a member of

Parliament for Roxburghshire 1880-92, and for the city of Durham 1898-1900. He has been editor of 'The Edinburgh Review' from 1895 and is the author of: 'Criminal Procedure in England and Scotland'; 'The State and the Church' (1881).

Elliott, Charles, American Methodist clergyman: b. Glenconway, County Donegal, Ireland, 16 May 1792; d. Mount Pleasant, Iowa, 3 Jan. 1869. He came to the United States in 1814 and became prominent in the Methodist denomination. He was a professor of languages at Madison College, Uniontown, Pa., 1827-31, and president of Iowa Wesleyan University 1856-60 and 1864-7. He published: 'Treatise on Baptism' (1834); 'Sinfulness of American Slavery' (1851); 'The Bible and Slavery'; etc.

Elliott, Charles Loring, American painter: b. Scipio, N. Y., December 1812; d. Albany, N. Y., 25 Aug. 1868. His works consist almost exclusively of portraits, many of which are of eminent American citizens, and are remarkable for the fidelity of the likeness and their vigorous coloring. In 1846 he became a member of the National Academy of Design.

Elliott, Charles Wylls, American novelist and historian: b. Guilford, Conn., 27 May 1817; d. 20 Aug. 1883. Settling in New York, he was one of the founders and trustees of the Children's Aid Society in 1853, and in 1857 was one of the commissioners for laying out Central Park. He published among other works: 'Cottages and Cottage Life' (1848); 'Mysteries, or Glimpses of the Supernatural' (1852); 'The Book of American Interiors'; 'Pottery and Porcelain'; 'Remarkable Characters and Places in the Holy Land'; 'St. Domingo, Its Revolution and Its Hero'; 'Wind and Whirlwind,' a novel; etc.

Elliott, Charlotte, English hymn-writer: b. 17 March 1789; d. Brighton 22 Sept. 1871. She wrote a number of religious poems, which were published under the titles: 'Hymns for a Week'; 'Hours of Sorrow'; 'Invalids' Hymn Book.' The last collection included 'Just as I Am,' a hymn which is widely used, and has been translated in "almost every living language."

Elliott, Ebenezer, English poet: b. Masborough, near Sheffield, 17 March 1781; d. Great Houghton, near Barnsley, 1 Dec. 1849. At first a foundry hand, his poetic gift was used in denouncing the exploitation of the proletariat by a capitalistic oligarchy; yet the bitterness and exaggerated rhetoric one would expect under such circumstances are wholly absent from 'Corn Law Rhymes' (1831), and 'More Prose and Verse' (1850). He was famed in his day as 'The Corn Law Rhymist.'

Elliott, Sir Henry Miers, English historian: b. Westminster 1808; d. Simon's Town, Cape of Good Hope, 20 Dec. 1853. Long an Indian civil servant, he compiled 'Memoirs of the History, Folk Lore, and Distribution of the Races of the Northwestern Provinces of India' (1869), and 'The History of India as Told by Its Own Historians: The Mohammedan Period' (1867-77).

Elliott, Henry Wood, American naturalist and artist: b. Cleveland, Ohio, 13 Nov. 1846. In 1862-78 he was private secretary to Joseph

ELLIOTT—ELLIPSIS

Henry, secretary of the Smithsonian Institution; in 1869-71 artist of the United States Geological Survey; and in 1872-4 and 1890 a special commissioner for the investigation of the Seal Islands of Alaska. His publications include: 'Monograph of the Seal Islands' (1881), and 'Our Arctic Province, Alaska' (1886); 'The Seal Islands of Alaska' (1894).

Elliott, Jesse Duncan, American naval officer: b. Maryland 1782; d. 1845. He entered the United States navy as a midshipman 1804, and in October of 1812 won the first American naval success on the lakes, capturing two British brigs, the *Detroit* and the *Caledonia*, near Fort Erie. He commanded the *Niagara*, in the battles of Lake Erie, September 1813, being second in command to Perry, whom he succeeded in October of the same year as commander of the Lake Erie fleet. In 1815, during the war against Algiers, he was in command of the sloop of war *Ontario*, under Decatur, being appointed captain in 1818.

Elliott, Maud Howe, American novelist: b. Boston, Mass., 9 Nov. 1855. She is a daughter of Julia Wood Howe (q.v.), and was married to John Elliott, an artist, in 1887. Her writings include: 'A Newport Aquarelle' (1883); 'The San Rosario Ranch' (1884); 'Atalanta in the South' (1886); 'Mammon' (1888); 'Honor'; and 'Phyllida.'

Elliott, Maxine, American actress: b. Rockland, Me. Making her début with E. S. Willard, she played Felicia Umfraville in 'The Middleman' (1890), and later in 'The Professor's Love Story.' She was with Rose Coghlan, and in 1895 went to London with Augustin Daly's company. A member of N. C. Goodwin's company 1896, she played in Clyde Fitch's 'Nathan Hale' (1898); was married to Mr. Goodwin that year, and appeared with him in 'When We Were Twenty-One,' playing Portia in 1901.

Elliott, Sarah Barnwell, American novelist. She is a granddaughter of Stephen Elliott (q.v.). Her best-known works are: 'The Felmers' (1879); 'Jerry'; 'John Paget'; 'Sam Houston'; 'The Durket Sperret' (1898); 'An Incident and Other Happenings' (1899).

Elliott, Stephen, American naturalist: b. Beaufort, S. C., 11 Nov. 1771; d. Charleston 28 March 1830. He was graduated at Yale College in 1791, and was president of the "Bank of the State" from 1812 till his death. His leisure hours were devoted to literary and scientific pursuits, and he cultivated the study of botany with enthusiasm. In 1825 he aided in establishing the medical college of the State, and was elected one of the faculty, and professor of natural history and botany. He was the author of the 'Botany of South Carolina and Georgia' (1821-4).

Elliott, William, American miscellaneous writer: b. Beaufort, S. C., 27 April 1788; d. there. He was educated at Yale, and devoted himself mainly to agriculture and rural sports. His published works include: 'Fiesco,' a tragedy (1850); and 'Carolina Sports by Land and Water' (1856).

Ellipse (Lat. *ellipsis*, from Gr. *elleipsis*, omission), a plane curve of such a form that, if from any point in it two straight lines be drawn to two given fixed points, the sum of

these straight lines will always be the same; a geometrical term used in conic sections. These two fixed points are called the foci. In the ellipse A B C D, E and F are the foci. If a straight line (E Q F) be drawn joining the foci, and be then bisected, the point of bisection is called the centre. The distance from the centre to either focus (E Q or Q F) is called the eccentricity. The straight line (G Q H), drawn through the centre and terminated both ways by the curve, is called the diameter. Its vertices are G and H. The diameter A C, which passes through the foci, is called the major axis; the points in which it meets the curve (A and

C), the principal vertices. The diameter (B D), at right angles to the major axis, is called the minor axis. Practically, a tolerably accurate ellipse may be drawn on paper by sticking two pins in it to represent the foci, putting over these a bit of thread knotted together at the ends, inserting a pencil in the loop, and pulling the sheet tight as the figure is described. The importance of the ellipse arises from the fact that the planets move in elliptical orbits, the sun being in one of the foci—a fact which Kepler was the first to discover.

The equation to an ellipse, referred to its centre as origin, and to its major and minor axes as rectangular axes, is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

where a and b are the semi-major and semi-minor axes respectively. From this equation it may be shown, by the integral calculus, that the area of an ellipse is equal to πab ; or is got by multiplying the product of the semi-major and semi-minor axes by 3.1416. It may also be shown that the length of the circumference of an ellipse is got by multiplying the major axis by the quantity

$$\pi \left\{ 1 - \left(\frac{1}{2} \right)^2 \frac{e^2}{1} - \left(\frac{1.3}{2.4} \right)^2 \frac{e^4}{3} - \left(\frac{1.3.5}{2.4.6} \right)^2 \frac{e^6}{5} - \&c., \right\}$$

to which there is an excellent practical approximation, namely:

$$\frac{\pi}{2} \left(a + b \sqrt{2(a^2 + b^2)} \right)$$

The eccentricity e , is $= \sqrt{1 - \frac{b^2}{a^2}}$ and the

ellipticity is the ratio $a-b$ to a .

Ellip'sis, in grammar, the omission of one or more words, which may be easily supplied by the connection. It is common, especially in colloquial language, for the sake of brevity, and frequently adds to the strength and perspicuity of the sentence. Hence a more extended use of the ellipsis in rhetoric and poetry. In the hands of a genuine poet or orator the ellipsis

has a very telling value. In natural language, from the brevity it affords, the ellipsis becomes in all its phases the language of passion, and especially of sudden and intense emotion; and the imitation of its natural use in this way is to the poet the most powerful instrument for painting passion to the life. The works of all the greater poets, and especially the Hebrew poetry of the Old Testament, abounds with familiar instances of this use of the ellipsis.

Ellip'soid, in geometry, a solid figure produced by the revolution of an ellipse about its axis, and all plane sections of which are ellipses or circles. The earth, generally said to be an oblate spheroid, has been designated also an oblate ellipsoid.

Ellis, Alexander John (originally Sharpe), English scientist and philologist: b. Hoxton 14 June 1814; d. London 28 Oct. 1890. He was educated at Shrewsbury, Eton, and Trinity, Cambridge, and devoted himself to mathematics, the scientific side of music, and more especially to philology and phonetics. His translation of Prof. Helmholtz's 'Sensations of Tone' (1875), has taken a place as a standard work on scientific music. In 1848 he published two small works: 'The Essentials of Phonetics'; and 'A Plea for Phonetic Spelling,' and collaborated with Sir Isaac Pitman (q.v.) in framing a phonetic system. His *magnum opus* on 'Early English Pronunciation,' with special reference to Chaucer and Shakespeare, appeared between 1869 and 1889.

Ellis, Edward Sylvester, American writer of school text-books and juvenile literature: b. in Geneva, Ohio, 11 April 1840. For some years he was superintendent of public schools at Trenton, N. J. Besides 'The People's Standard History of the United States' and several school histories, his works include: 'The Boy Pioneer Series' (1883-4); 'The Camp Fires of Gen. Lee' (1887); 'The Hunters of the Ozark' (1887); 'The Great River Series' (1888); 'Storm Mountain,' and many other juveniles.

Ellis, George, English author: b. London, England, 1745; d. April 1815. He was educated at Westminster School and Trinity College, Cambridge, and was one of the junta of wits concerned in the well-known political satire, 'The Rolliad.' He published: 'Specimens of the Early English Poets, with an Historical Sketch' (1790); 'Specimens of Early English Metrical Romances' (1805); and was an intimate friend of Sir Walter Scott.

Ellis, George Edward, American Unitarian clergyman and historical writer: b. Boston, Mass., 8 Aug. 1814; d. there 20 Dec. 1894. He was pastor of the Harvard (Unitarian) Church, Charlestown, Mass., 1840-69; and held the professorship of systematic theology in the Cambridge Divinity School 1857-63. As president of the Massachusetts Historical Society he made valuable contributions to early colonial history. He published: 'A Half-Century of the Unitarian Controversy' (1857); 'History of the Battle of Bunker's Hill' (1875); 'The Red Man and the White Man' (1882); 'The Puritan Age and Rule in the Colony of Massachusetts Bay, 1629-85'; various memoirs, and several biographies in Sparks' 'American Biography.'

Ellis, Henry Havelock, English scientist and literary scholar: b. Croydon, Surrey, 2 Feb.

1859. He taught school in New South Wales 1875-9, and on his return to England practised medicine for a short time and then devoted himself to literary and scientific work. He is a Fellow of the Medico-legal Society of New York, and honorary Fellow of the Chicago Academy of Medicine, and has been general editor of the 'Contemporary Science Series' from 1889. He edited the 'Mennaid Series of Old Dramatists' (1887-9); and is the author of 'The New Spirit' (1890); 'The Criminal' (1890, enlarged 1901); 'Man and Woman: a Study of Human Secondary Sexual Characters' (1894); 'Sexual Inversion,' being Vol. I. of 'Studies in the Psychology of Sex' (1897); 'Affirmations' (1897); 'The Evolution of Modesty,' being Vol. II. of 'Studies in the Psychology of Sex' (1899); 'The 19th Century: a Dialogue in Utopia' (1900); 'Analysis of the Sexual Impulse,' being Vol. III. of 'Studies in the Psychology of Sex' (1902).

Ellis, Job Bicknell, American botanist: b. Potsdam, N. Y., 1829. With B. M. Everhart he has published: 'North American Pyrenomyces' (1892); and 'North American Fungi' (1878-93).

Ellis, John, English naturalist: b. London about 1710; d. 1776. He was the first who suggested the idea that the South Sea islands were constructed and raised from the bottom of the ocean by means of zoophytes or the polypi inhabiting different species of coral ('Essay Towards a Natural History of Corallines' 1754). He was for some time agent for the colony of West Florida and the island of Dominica. Among his works is a posthumous one entitled 'The Natural History of Many Curious and Enormous Zoophytes' (1786).

Ellis, Robinson, English classical scholar: b. Barming, Kent, 5 Sept. 1834. He was educated at Rugby and Balliol College, Oxford; and in 1870 became professor of Latin in University College, London. From 1883 till 1893 he was university reader in Latin literature at Oxford, and in the latter year he was elected to the corpus professorship of Latin. His name is chiefly associated with the elucidation of the poems of the Roman poet Catullus. In 1867 he published a critical edition of Catullus ('Catulli Veronensis Liber'), and in 1871 'The Poems and Fragments of Catullus' in the metres of the original, these works being followed by a 'Commentary on Catullus' (1876). Other publications of his include: Ovid's 'Ibis,' with commentary (1881); 'Fables of Avianus' (1887); 'Noctes Manilianæ' (1891); 'The Fables of Phædrus' (1894); and a new recension of 'Velleius Paterculus,' with commentary.

Ellis, Sarah Stickney, English author: b. London, England, 1812; d. Hoddesdon, Herts, 16 June 1872. She was the wife of William Ellis (q.v.). Among her works the best known are: 'Women of England' (1838); and 'Daughters of England' (1842). Still others are: 'Poetry of Life' (1838); 'Summer and Winter in the Pyrenees' (1841); 'The Island Queen' (1846), a poem; 'Fireside Tales' (1848); 'The Brewer's Family' (1863); 'William and Mary' (1865); 'Northern Roses.'

Copyright by C. E. Anderson, Sec'y, 1901.

OLIVER ELLSWORTH.

CHIEF JUSTICE OF THE UNITED STATES SUPREME COURT, 1796-1800.

Ellis, T. Mullett, English poet and novelist: b. 29 Dec. 1850. He is the founder and editor of 'The Thrush,' a magazine for original verse, and has published: 'The Earl's Nose,' humorous verse; 'Reveries of World History' (1893); 'The Beauty of Boscastle' (1894); 'Zalma' (1895); 'Tales of the Klondike'; 'God is Love' (1898); 'Kitty, a Story of the Transvaal War'; etc.

Ellis Island, a small island owned by the United States government, and used as an immigrant station. It is situated in New York Bay, one mile southwest of the Battery, where the old immigrant station, Castle Garden, was located. The United States immigrant commissioner has his offices on this island. Immigrants detained for investigation as to compliance with the United States immigration laws, are kept on this island until allowed to land or are deported. See IMMIGRATION LAWS.

Ellora, ẽ-1ẽ'rã, **Elora**, or **Eluru**, ẽ-loo'rã, India, village in the province of Aurungabad; celebrated for some remarkable cave temples, excavated in the solid rock, which in magnitude and perfection surpass all other constructions of the kind in India.

Ellore, ẽ-lõr', India, town, in the Godavari district of the Madras presidency, on the river Jammaler, once the capital of the Northern Circars. It has magisterial and judicial establishments, police station, post-office, etc., a number of Christian missions, and a garrison. There are some manufactures of carpets and salt-petre. Pop. 29,382.

Ells, Robert Wheelock, Canadian geologist: b. Cornwallis, N. S., 26 July 1845. He was graduated at McGill University in 1872, and in May of that year joined the staff of the Canadian Geological Survey, of which he later became senior geologist. He is the author of numerous reports on geology and mineral resources, published in the annual volumes of the Canadian Geographical Survey since 1872.

Ells'worth, Ephraim Elmer, American soldier: b. Mechanicsville, N. Y., 23 April 1837; d. Alexandria, Va., 24 May 1861. He organized about 1859 a zouave corps which became noted for the excellence of its discipline. In March 1861 he accompanied President Lincoln to Washington, and in April he went to New York, where he organized a zouave regiment of firemen, of which he became colonel. Ordered to Alexandria, he lowered a Confederate flag floating over a hotel, for which act the hotelkeeper shot him dead.

Ellsworth, Oliver, American jurist: b. Windsor, Conn., 29 April 1745; d. there 26 Nov. 1807. He was graduated at the College of New Jersey in 1766, and soon after commenced the practice of law. In 1777 he was chosen a delegate to the Continental Congress, and in 1780 was elected a member of the council of Connecticut, in which body he continued till 1784, when he was appointed a judge of the superior court. In 1787 he was elected to the convention which framed the Federal Constitution, and was afterward a member of the State convention, where he earnestly advocated the ratification of that important instrument, which his exertions had essentially aided in producing. In 1789 he was chosen a senator of the United

States, which station he filled till 1796, when he was nominated by Washington chief justice of the Supreme Court of the United States. In 1799 he was appointed envoy extraordinary to Paris, and with his associates successfully negotiated a treaty with the French. He resigned his office of chief justice in 1800.

Ellsworth, Timothy Edwards, American soldier and politician: b. East Windsor, Conn., September 1836; d. Buffalo, N. Y., 10 Feb. 1904. He was admitted to the bar in 1858, and at the outbreak of the Civil War recruited a company of cavalry, of which he was made captain, and which became a part of the 7th N. Y. cavalry. He practised law at Lockport, and was elected to the State Senate in 1881, 1883, 1895, 1898, and 1900, being at one time speaker *pro tem.* and Republican leader.

Ellsworth, Maine, city, port of entry and county-seat of Hancock County, on both sides of the Union River, and on the Maine C. R.R.; 29 miles southeast of Bangor. It is the trade centre of the county and has extensive timber, ice, ship-building, and fishing interests, exporting over 50,000,000 feet of lumber annually. It has shoe, woolen, leather, and other manufacturing industries, a public high school, custom house, court-house, public library, two national banks, and two weekly newspapers. Pop. (1900) 4,297.

Ell'wanger, George Herman, American author: b. Rochester, N. Y., 10 July 1848. He was educated in Europe and has devoted himself mainly to literature. His published works are: 'The Gardener's Story, or Pleasures and Trials of an Amateur Gardener' (1889); 'The Story of My House' (1891); 'In Gold and Silver' (1892); 'Idyllists of the Country Side' (1896); 'Meditations on Gout, With a Consideration of Its Cure Through the Use of Wine' (1898); 'Love's Demesne, a Garland of Contemporary Love Poems' (edited 1896).

Ell'wood, Thomas, English Quaker: b. Crowell, near Thame, Oxfordshire, 1639; d. Amersham 1 March 1714. About 1660 he was induced to join the Society of Friends, and subsequently became reader to Milton, with whom he improved himself in the learned languages, but was soon obliged to quit London on account of his health. In the year 1665 he procured a lodging for Milton at Chalfont, Bucks, and was the occasion of his writing 'Paradise Regained' by the following observation made on the return of the 'Paradise Lost,' which the poet had lent him to read in manuscript: 'Thou hast said much of paradise lost, but what hast thou to say of paradise found?' In 1705 he published the first part of 'Sacred History, or the Historical Parts of the Old Testament'; and in 1709 'Sacred History, etc., of the New Testament.' His other works are numerous; among them 'Davideis, the Life of David, King of Israel, a poem, which is more distinguished for piety than poetry. His life, written by himself, and published the year after his death, affords many interesting particulars of the history of his sect.

Elm, *Ulmus*, a genus of trees and a few shrubs of the natural order *Ulmaceae*. The species, of which about 20 are known, are natives of the north temperate zone and the southern portions of the Arctic zone. Their

ELM — ELM-INSECTS

southern limits seem to be the Himalayas in Asia and the mountains of southern Mexico. None are natives of the Pacific slope. They are characterized by short petioled, alternate, rough, usually deciduous, leaves with serrate edges; axillary racemes of perfect, apetalous flowers which appear in early spring, before or with the leaves; and compressed, winged, dry fruits (nutlets). Many of the species are of wide economic importance. Their hard, heavy, tough, pliable wood is largely used in the manufacture of barrels, agricultural implements, boats, wagon wheels, buildings, etc., and for fuel. The inner bark of some species furnishes an article of food, and that of others a tough bast fibre used for cordage and cloth making. The outer bark of others is used in dyeing and sugar refining. Various parts of several species were formerly popular remedies employed in medicine, but except in domestic and local practice are rarely prescribed. Most of the species are highly valued as ornamental trees in street and park planting, those specially popular being the straight trunked, tall growing, vase-formed species, which quickly over-arch the streets and cast an abundant shade. Many cultivated varieties of fantastic form, color of foliage or habit of growth are also planted as curiosities.

The best-known American species is probably the white, water, or American elm (*U. alba* or *Americana*), which grows in rich moist woods, especially on the shores of streams from Newfoundland to Florida and westward to the eastern side of the Rocky Mountains. It is a tall tree, often attaining a height of 120 feet when growing in the forest, and a wide-spreading, less lofty top when growing in the open, where it may be seen in several different forms, popularly known as vase, plume, oak-tree, etc., according to the arrangement of the branches. Some specimens of each form develop numerous twiggy growths upon the trunk and main branches, which are thus rendered very attractive because of their feathery appearance. The most common form is the vase, in which the main branches develop at about 20 feet or more, and at their bases gradually, and toward their extremities widely diverge. This is probably the most popular street form and species in America. Another well-known American species is the slippery or red elm (*U. fulva* or *rubra*), which attains a height of 70 feet in rich soils and is found from Quebec to Florida and westward to Texas and Dakota. It is called red because the bud scales are reddish and conspicuous when unfolding in spring; and it is called slippery because of its mucilaginous inner bark. Its wood is less valued than that of the English elm, but more than that of the white elm. The cork or rock elm (*U. racemosa*), which grows on river banks from New England to Nebraska and as far south as Kentucky and Tennessee, attains a height of 100 feet and is noted for the corky developments resembling wings on the smaller branches. Its wood is specially valued for its great durability, strength, pliability, and toughness. Another species with corky, winged branches is the Wahoo or winged elm (*U. alata*), which ranges from Virginia to Florida and westward to Texas and Illinois. It rarely exceeds 70 feet in height, is very attractive in habit, and is planted for ornament in the South,

but not in the North, as it is not sufficiently hardy for the rigors of winter.

The most noted European species is the English elm (*U. campestris*), which ranges through middle and southern Europe, northern Africa, and eastward to Japan. It reaches 100 feet in height and has a rather round-topped or open head, on account of its spreading branches. It is frequently planted for ornament at home and abroad, and in America is valued because its foliage continues green for several weeks after that of the white elm. It has several distinct varieties, which are sometimes considered as distinct species, and of which there are a large number of horticultural varieties. The next most important European species is probably the Scotch or wych elm (*U. scabra* or *montana*), which has much the same range as the preceding species, like which it attains a height of about 100 feet. It is a variable species with many cultivated varieties, one of the best known of which is the Camperdown elm, which has long, pendulous branches, on account of which the tree is frequently planted as a curiosity in parks and gardens. The Chinese elm (*U. parvifolia*) is a semi-evergreen shrub or small tree, a native of eastern Asia, which has proved hardy in America as far north as Massachusetts.

Elms are readily propagated from seed which ripens in late spring or early summer and should be sown at once. The seedlings are easily managed, both as to cultivation, transplanting and pruning. The trees do best in rich soil, especially if moist. The choice varieties are generally grafted. The trees, especially of the American or white elm, are specially liable to the attacks of certain insects and diseases, which often defoliate them. The latter may be kept in check by the timely and proper application of a standard fungicide (q.v.).

The name elm is also given to various unrelated trees, the best known of which are probably the following: Water elm (*Phanera aquatica*); Spanish elm or Bois-de-Chypre (*Cordia gerascanthus*), and also to *Hamelia verticosa*, both of which species are natives of the West Indies. Several Australian trees are also known as elms, especially *Duboisia myoporioides* and *Aphananthe Philippinensis*, each of which is valued for its timber.

Elm, Slippery, in medicine, the bark of *Ulmus fulva*, is widely used as a demulcent. It is probable that the ancient Indian inhabitants of the country introduced it into modern medicine. Slippery elm bark is noted for the large amount of mucilage which it contains, thus rendering it a pleasing demulcent for sore throat, diarrhoea, dysentery, and inflammation of the intestinal tract in general.

Elm-insects. Few ornamental trees are more subject to the attacks of insects than are the elms, and especially the American elm. The European species are, however, attractive to the European insects, of which many have been brought over unintentionally, and have spread remarkably because of the absence of their enemies. One of the most notable is the plant-louse known as *Colopha ulmicola*, which produces the cockscomb galls upon the foliage. It is rarely very troublesome, and has usually done its damage before it can be attacked. Kerosene emulsion, if applied in time, will prove

ELM TREES.

FAMOUS NEW ENGLAND ELMS.

effective. (See INSECTICIDE.) A borer (*Saperda tridentata*) is sometimes troublesome, but there seems to be no satisfactory way to control it. Most of the other insects that attack the elms are beetles, their larvæ, or the caterpillars of various moths. These all bite their food, and hence may be attacked with arsenites or other stomach poisons sprayed upon the foliage. Among these insects are the four-horned sphinx-moth (*Ceratomia amyntor* or *quadricornis*), a green caterpillar with four little horns near the head and the long anal horn characteristic of the sphinx-moth. The bag-worm (*Thyridopteryx ephemeraformis*), the gypsy-moth (*Ocneria dispar*), the tussock-moth (*Notolophus* or *Orgyia leucostigma*), and several other general feeders are frequently troublesome. But the most important leaf-eating enemy of the elm is the elm-leaf beetle (*Galeruca xanthomelana*), a greenish-yellow, two-striped European insect which appears and eats the leaves in spring. The bottle-shaped yellow eggs are laid in rows on the under sides of the leaves, and the hairy, black-spotted, yellow larvæ eat circular holes between the leaf-veins. Spraying with arsenites is effective, but where more than one brood is produced the sprayings must be repeated frequently throughout the summer. Consult Marlatt, 'Elm Leaf Beetle,' Circular 8, Division of Entomology, United States Department of Agriculture.

Elmer, Horace, American naval officer: b. Bridgeton, N. J., 1847; d. Brooklyn, N. Y., 27 April 1898. He entered the navy as acting midshipman in September 1861, and reached the rank of commander in 1885. During the winter of 1897-8 he superintended the construction of naval vessels at Cramp's shipyard in Philadelphia. When it became evident that war with Spain would break out, he was ordered to organize the naval force afterward known as the "mosquito fleet" for coast patrol duty.

Elmina, ɛl-mě'nā, or **St. George del Mina**, West Africa, a town belonging to Great Britain, formerly the capital of the Dutch settlements on the Gold Coast, five or six miles west of Cape Coast Castle. The Castle of Saint George del Mina was the first European establishment on the coast of Guinea, having been erected by the Portuguese in 1481. Pop. 10,530.

Elmira, N. Y., city, county-seat of Chemung County, on both sides of the Chemung River, and on the Delaware and Lackawanna, the Lehigh Valley, the Northern Central, and the Erie railways; 100 miles southeast of Rochester, 149 miles east-southeast of Buffalo, and 46 miles south-southwest of Ithaca.

Industries, etc.—The government census for 1900 records a total of 362 industrial establishments, with a capital of \$7,365,534, the average number of wage-earners being 4,914, with total wages of \$1,965,056. Among the more important establishments are railway car and general construction and repair shops, steel-plate works, boot and shoe manufactories, glass works rolling-mills, fire-engine construction works, boiler and engine shops, lumber and planing mills, sash, door and blind factories, breweries, tobacco warehouses and factories of tobacco products, iron and steel bridge works, dye-works, silk-mills, knitting-mills, and hardwood-finishing works. The district is fertile, and there are also stone-quarries in the vicinity.

Public Institutions, Buildings, etc.—Here are located Elmira College (q.v.), a State armory, the State reformatory (see ELMIRA REFORMATORY), the Arnot-Ogden Memorial Hospital, the Steele Memorial Free Library, a Federal government building housing the Federal courts, the post-office, etc., and various charitable institutions. The park system includes Wisner, Riverside, Eldridge, and Hoffman parks. Elmira is finely laid out, and has an excellent water supply, and gas and electric lighting.

History, Government etc.—Elmira was permanently settled in 1788, was incorporated as the village of Newtown in 1815, and in 1828 was re-incorporated as the village of Elmira. In 1836 it became the county-seat of Chemung County, and in 1864 obtained its city charter. During the Civil War it was the State recruiting and military rendezvous, and in 1864-5 one of the Federal prisons for Confederate prisoners of war was here situated. Near the present site of Elmira the battle of Newtown was fought, 29 Aug. 1779. General Sullivan, with an American force numbering 5,000, defeating a combined band of Tories and Indians commanded respectively by Sir John Johnson and Joseph Brant (Thayendanegea) and numbering approximately 1,500. The battle-ground is now marked by a memorial to Sullivan. Elmira is governed, under a charter of 1894, by a mayor, who is biennially elected, and a common council, which is unicameral. In addition to the aldermen, who are chosen by wards for terms of two years, the recorder, municipal judge, and 12 supervisors, to act as a county board, are also chosen by popular vote. Pop. (1890) 30,893; (1900) 35,672; (1903 est.) 37,106.

Elmira, Battle of, 29 Aug. 1779, in the Revolution. See CHEMUNG, BATTLE OF.

Elmira College, an institution for women, located in Elmira, N. Y. It was founded in 1855 under the auspices of the Presbyterian Church, and its course of study from the first demanded as high a grade of work as is usual in first-class colleges. The degrees conferred are bachelor of arts, bachelor of science, bachelor of music, and master of arts.

Elmira Reformatory, a State institution, located in Elmira, N. Y. It is a reformatory to which may be sent only men between the ages of 16 and 30 who have not served a period in a State prison. The court of the State of New York, in sentencing a prisoner to this institution, has no authority to limit the time; that is determined by the managers of the institution, and is almost wholly dependent upon the conduct of the prisoner. However, the term of imprisonment shall not, according to the law of the State, "exceed the maximum term provided by law for the crime for which the prisoner was convicted and sentenced." This reformatory, which takes the place of a State prison for male offenders who have not become hardened in crime, has effected a radical change in methods of dealing with the class of law-breakers intended to benefit. (See BROCKWAY, Z. R.) Consult: Winter, 'The Elmira Reformatory'; New York State Laws of 1877, sec. 2, ch. 173.

Elmo, Ermo, or Erasmus, Saint, a martyr who suffered death at Formiæ, a town of ancient Italy, during the persecution under Diocletian, in 303. He is considered the patron saint of

sailors, and is usually invoked by Italian sailors during a storm. His feast is kept on June 3.

Elmo's Fire, Saint, is the popular name of an electric appearance sometimes seen, especially in southern climates during thunderstorms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is also observed at the tops of trees, on the manes of horses, and occasionally about human heads. It is similar in kind to the luminous glow seen at the point when a lightning-rod is working imperfectly, or when there is any very rapid production of electricity. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux, and was regarded as of friendly omen. The name Elmo is by many thought to be a corruption of that of Helena, the sister of Castor and Pollux. Others take it to be a corruption of Saint Erasmus (Italianized, *Ermo, Elmo*), a Syrian bishop and martyr of the 3rd century, who is invoked by Mediterranean sailors during storms. The phenomenon has also been called the fire of Saint Elias, of Saint Clara, of Saint Nicholas, and of Helena, as well as composite, composant or corposant (that is, *corpus sanctum*).

El'more, Alfred, Irish artist: b. Clonakilty, Ireland, 18 June 1815; d. London 24 Jan. 1881. He studied at Royal Academy, London, traveled through Europe to Rome, where he lived two years, returned to England 1844, becoming an associate of the Royal Academy 1845, and Royal Academician 1856. Among his works are: 'Martyrdom of Thomas à Becket' (1840), St. Andrew's Church, Dublin; 'The Novice' (1843); 'Rienzi' (1844); 'Death of Robert, King of Naples' (1848); 'Griselda' (1850); 'Charles V. at Yuste' (1856); 'Marie Antoinette in the Temple' (1861); 'Louis XIII. and Louis XIV.' (1870); 'Ophelia' (1875); 'Mary Queen of Scots and Darnley' (1877); 'Pompeii,' 'John Alden and Priscilla' (1878); 'After the Ruin,' and 'Lenore.'

Elms, City of, a popular name given to New Haven, Conn.

Elmshorn, ělmz'hörn, Germany, town in Sleswick-Holstein, 20 miles northwest of Hamburg, on the railway to Kiel, and on the Krückau, a navigable tributary of the Elbe. It carries on a considerable amount of traffic by land and water, and has manufacturing industries of various kinds, such as leather, boots and shoes, machinery, dyeing, linen- and cotton-weaving, distilling and brewing, etc. Pop. 13,720.

Elobey (a-lô-bâ'ë) Islands, the name of two small islands off the coast of Guinea, in Africa, both of which belong to Spain. On Elobey Chico, the smaller island, there is a missionary school, and some manufacturing has been begun. Elobey Grande is the larger island. Pop. of both (1901) 350.

Elocution, the art of correct speaking or reading in public, including the appropriate use of gestures. Great attention was paid by the ancients to this art as a branch of oratory. The rhetors in Greece had schools in which young men were trained in the correct use of the voice. Many of the Romans were sent to Greece to study and afterward there were similar teachers of elocution and oratory

in Rome. In modern times the stage has fostered the study of elocution and special attention has been given to it in the Paris Conservatoire, where the strictest canons of the art have been maintained. Many colleges have established professorships of elocution, and it is also one of the branches in the curriculum of well-regulated conservatories of music. The tendency of modern teachers is toward greater simplicity and naturalness of gesture and repose of manner than was formerly used. Perhaps the most successful teacher of this century was Delsarte (q.v.), whose theories and practice worked a revolution both in France and other countries. Notable schools of elocution have been established in this country by Charles Wesley Emerson, Franklin H. Sargent, and others. The list of distinguished elocutionists includes the names of Munroe, Riddle, Riley, Powers, and Mackaye. See ORATORY.

Eloge, ā-lôzh (French), is a discourse pronounced in public in honor of the memory of an illustrious person recently deceased. In modern times the éloge is peculiarly a French institution, and has given rise to a quite distinct species of literature, which, though its style is not the most agreeable, is not altogether without utility, as the best éloges frequently contain rapid and summary views of the state of science, art, literature at a particular time, of the works of some distinguished author, the political events of a period, or whatever other theme may be suggested to the orator by the particular career of the subject of his eulogy. The éloges of Fontenelle (1731), and of Cuvier (1819), are particularly valuable and interesting. Such summaries, of course, considering the object with which they are made, must be received with great caution, but they frequently convey information not easily accessible in other ways. An éloge is pronounced over every member of the French Academy when he dies, as the inaugural discourse of the new member who is chosen to succeed him. The abuses to which this style of composition is liable have given rise to burlesque and satirical éloges.

Elohim, ěl'ô-hîm or ě-lô'hîm (plural of Eloah), one of the Hebrew names for God, of frequent occurrence in the Bible, especially in those parts of the Pentateuch attributed to the earliest writers in the northern domain of the Semitic race. Elohim is used in speaking both of the true God and of false gods, while Jehovah is confined to the true God. The plural form of Elohim (literally signifying "the great Eloah" or God) has caused a good deal of controversy among critics. By some it has been considered as containing an allusion to the doctrine of the Trinity, others regard it as the plural of excellence, while others hold it as establishing the fact of a primitive polytheism. This word, along with Jehovah, has played a great part in modern criticism. Critics have professed to find in the comparative frequency of the two terms an evidence of the date of the manuscripts in which they occur; but on this controversy we cannot enter. See ELOHIST.

Elohîst, ěl'ô-hîst, also called **Yahwîst**, both used in contradistinction to Jehovist (q.v.), one of the Biblical writers, hypothetically assumed to have written part of the Pentateuch, who habitually, if not exclusively, used the

ELONGATION — ELSINORE

Hebrew name *Elohim* for God. The Elohist passages in the Old Testament, as determined upon by Biblical scholars, are simple, straightforward, and bear no signs of rhetoric or poetic effort, therein contrasting with the Jehovistic paragraphs. Gen. i. 27 is Elohist; Gen. ii. 21-4 is Jehovistic. See BIBLE.

Elongation, in astronomy, the angle that measures the apparent distance of two stars as seen from the earth. The term is, however, by usage confined exclusively to the distance of a planet from the sun, and of a satellite from its primary. The greatest elongation of Mercury amounts to about $28^{\circ} 30'$; that of Venus to about $47^{\circ} 48'$, and that of the superior planets may have any value up to 180° . When two fixed stars or planets are spoken of the word "distance" is employed.

Elopement, an act of unlicensed departure, especially when a wife forsakes her husband and flees with a paramour, or when a daughter or ward accepting the protection of a lover leaves her natural or legal guardians. In almost every one of the States, the male principal in an elopement is held guilty of an abduction provided his associate in the act is under age. Marriage, however, checks all consequent criminal proceedings unless the female alleges coercion. All persons guilty of aiding or abetting an elopement of a male with a female are deemed in law accessories, and liable to legal proceedings. Elopers themselves are not safe from arrest, their act coming within the purview of the criminal statutes.

Elothrium, an extinct suilline animal of the Oligocene Epoch, remotely related to the hippopotami and pigs. The skull suggests that of the hippopotamus, but it has a narrow elongated muzzle; and the front teeth resemble those of the carnivora rather than the shearing tusks of the hippopotami and pigs. The limbs and feet are tall and stilted, the lateral toes reduced to small rudiments, as in ruminants. Different species ranged in size from that of a sheep to that of a rhinoceros.

El Petén, Guatemala, one of the northern departments of the republic; pop. 6,752. Its chief town is Flores; pop. 1,671, and altitude above sea 482 feet.

Elphinstone, Mountstuart, East Indian administrator: b. Scotland 6 Oct. 1779; d. Limpsfield, Surrey, 20 Nov. 1859. He joined the Bengal civil service in 1795; was ambassador to the Afghan court in 1808; resident at the court of Poonah from 1810 to 1817; and British commissioner to that province from 1817 to 1819, when he became governor of Bombay. During a government of seven years he established a code of laws, lightened taxes, and paid great attention to schools and public institutions. He resigned in 1827. A college established by the natives was called after him Elphinstone College. He was the author of an 'Account of the Kingdom of Cabul and Its Dependencies' (1815); and a 'History of India' (1841).

Elphinstone, William, Scottish prelate: b. Glasgow 1431; d. 25 Oct. 1514. Having gone to France he studied law for three years, and was appointed professor of law, first at Paris and subsequently at Orleans. He was subsequently made commissary of the Lothians, and in 1479 was made archdeacon of Argyle. Soon after he

was made bishop of Ross; and in 1483 was transferred to the see of Aberdeen. In 1488 he was made lord high-chancellor of the kingdom. In October of that year he assisted in the coronation of James IV. He was afterward sent on a mission to Germany, and on his return was installed in the office of lord privy-seal, which he held till his death. In 1494 he obtained a papal bull for the erection of a university at Aberdeen, and King's College and University soon came into existence.

El Quicke, Guatemala, one of the northern departments of the republic; pop. 92,753. Its chief town is Santa Cruz; pop. about 12,000 and altitude above sea-level 5,543 feet.

Elsberg, *ëlz'bërg*, **Louis**, German-American physician: b. Gerlohn, Prussia, 1836; d. in the United States in 1885. He introduced the art of laryngoscopy in the United States, wrote many papers on the throat and its diseases, notably, 'The Throat and the Production of the Voice'; was the first to illustrate the character of undertones and divisions of sound in articulation, and invented many instruments which are used in surgical treatment of the throat and ear.

Elsheimer, *ëlz'him-ër*, **Adam**, German painter: b. Frankfort-on-the-Main 1578; d. probably at Rome 1620, called the "Roman Painter of Germany." He studied in Rome and settled there while still very young. He painted many biblical and mythological scenes and was a master of landscape, being the chief German artist of the end of the 16th century to acclimatize Roman art in Germany. Among his principal works are: 'Jupiter and Mercury with Philimon and Baucis'; 'Joseph in the Pit'; and 'Judith,' at Dresden; 'Martyrdom of St. Lawrence,' and 'Flight into Egypt,' at Munich; his portrait and 'Triumph of Psyche' at Florence; many landscapes at Naples, Venice, and Madrid; 'Good Samaritan,' and another 'Flight into Egypt' at the Louvre, and a large collection of drawings.

Elsie Venner, a romance by Oliver Wendell Holmes, first published serially, in 1859-60, under the name of 'The Professor's Story.' It is a study in heredity, introducing a peculiar series of phenomena closely allied to such dualism of nature as may best be described by the word "ophianthropy." Delineations of the characters, social functions, and religious peculiarities of a New England village, form a setting for the story. The victim of some pre-natal casualty, Elsie shows from infancy unmistakable traces of a serpent-nature intermingling with her higher self. This nature dies within her only when she yields to an absorbing love.

Elsinore, *ël-si-nör'*, or **Elsineur** (Danish, Helsingör), Denmark; seaport, on the island of Zealand; 24 miles northeast of Copenhagen. Its inhabitants are engaged chiefly in commerce and seafaring. The castle of Kronborg, built about 1580, is the chief defense of the town. It is a Gothic-Byzantine edifice, built by Frederick II. in the boldest style, and is said to be one of the finest structures of its kind in Europe. It is now chiefly used as a prison, and was the place of confinement of the unfortunate Matilda, sister of George III. of England. The manufactures are chiefly fishing-nets and a coarse cloth. Ship-building has been an important industry. Pop. (1901) 13,902.

ELSON — ELVES

Elson, Henry William, American author: b. Muskingum County, Ohio, 29 March, 1857. He was educated at Lutheran Theological Seminary, Philadelphia, and the University of Pennsylvania. After occupying two or three Lutheran pastorates he left the ministry and took up the work of writer and lecturer of the University Extension Society of Philadelphia. He has published 'Side Lights on American History' (1899); 'Four Historical Biographies for Children: Andrew Jackson, U. S. Grant, Daniel Boone, and Frances Willard' (1899); 'How to Teach History' (1901), and 'Elson's History of the United States.'

Elson, Louis Charles, American writer on music: b. Boston, Mass., 17 April 1848. After studying music at Leipsic he returned to Boston and has been a teacher and lecturer on music there from 1876. He has been musical editor of the *Boston Advertiser* since 1888. He has published 'Curiosities of Music' (1883); 'German Songs and Song Writers' (1886); 'Our National Music and Its Sources' (1886); 'Theory of Music' (1890); 'Realm of Music' (1892); 'European Reminiscences' (1893); 'Great Composers' (1897); 'Shakespeare in Music' (1900); 'Famous Composers and Their Works,' new series (1901).

Elssler, ěl'z'ler, Fanny, Austrian dancer: b. Vienna 23 June 1810; d. there 27 Nov. 1884. She was the daughter of Johann Elssler, Haydn's factotum, and was educated at Naples for the ballet, with her elder sister Theresa, who in 1851 became the morganatic wife of Prince Adalbert of Prussia and was ennobled. Fanny Elssler during her visit to the United States gave an entertainment in order to raise money for the Bunker Hill Monument.

Elster, ěl'stěr, two German rivers. (1) The White, or Great Elster, rising in the west of Bohemia, flows north into Saxony, receives the Pleisse and Parde at Leipsic, and joins the Saale between Halle and Merseburg, after a course of about 115 miles. (2) The Black Elster, rising in Saxony, flows north into Prussia, then northwest, receives the Pulsnitz and Röder, and joins the Elbe between Wittenberg and Torgau, after a course of about 130 miles.

El'stracke, Reginald or Ronald, English engraver: b. probably in London and lived there early in the 17th century. His plates were made with the graver solely, their chief value being historical. He executed portraits of Mary Queen of Scots, Darnley, and Queen Elizabeth. Among his works was a volume of 32 plates called 'Basiliologia: a Book of Kings, being the true and lively effigies of all our English Kings from the Conquest until this present' (1618).

Elswick, ěl'z'wik, England, suburb of Newcastle, containing the great ordnance works of Sir William Armstrong, Mitchell & Company. These works are probably the largest of their kind in Europe, and employ about 14,000 persons. Pop. 51,000.

El'ton, Charles Isaac, English jurist and archæologist: b. Somerset 1839; d. Chard, Somerset, 23 April 1900. He was educated at Oxford and was called to the bar in 1865. He represented West Somerset in Parliament as a Conservative 1884-5 and 1886-92. On

legal subjects he published: 'Tenures of Kent' (1867); 'Commons and Waste Lands' (1868); 'Copyholds and Customary Tenures' (1874-93); 'Improvement of Commons Bill' (1876); 'Custom and Tenant-Right' (1882); and 'Robinson on Gavelkind' (1897). Other works of his are: 'Norway, The Road and Fell' (1864); 'The Career of Columbus' (1892); 'The Great Book-Collectors' (1893); and 'Shelley's Visits to France' (1894). His greatest work, however, is his 'Origins of English History' (1882). It is chiefly characterized by its thorough investigation of the evidence furnished by Greek and Roman writers regarding the condition and circumstances of early Britain, by its discussion of the ethnology and prehistoric archæology of the country, and by the importance assigned to the Celtic and even pre-Celtic element in forming the English nation.

Elton, James Frederick, English explorer: b. 3 Aug. 1840; d. 13 Dec. 1877. He entered the Indian Army in 1857. In 1871 he found himself in the Transvaal and Natal; in 1873 he was vice-consul at Zanzibar, two years afterward as consul in Mozambique he explored the coast of East Africa for the sake of repressing the slave trade. With Cotterill he reached Lake Nyassa in 1877 and scaled the Konde range of mountains at the north end of the lake, to the height of 10,000 feet. After his death Cotterill published his journal under the title: 'Travels and Researches among the Lakes and Mountains of Eastern and Central Africa.'

Elton, a shallow lake in the government of Astrakhan, in Russia; area, 60 square miles. Eight salt-water streams flow into this lake, and it has no visible outlet; thus a large salt deposit rests on the bed of the lake. From about the middle of the 17th century for 100 years, the salt from this lake was in demand; but since the opening of the salt fields in the southern part of Russia (1860) the Elton salt has not been on the market.

Elvas, ěl'väs (Rom., ALPESA; Moorish, BALESH), the strongest fortified city of Portugal, in the province of Alemtejo, near the Spanish frontier; 10 miles west of Badajoz. Standing on a hill, it is defended by seven large bastions and two isolated forts. Pop. (1900) 14,018.

Elves (O. Eng., *ělf*; Germ. *Alp*; phantom, spirit); imaginary creatures of the northern mythology, forming, according to some classifications, with the undines, salamanders, and gnomes, groups of elementary sprites identified respectively with the water, fire, earth, and air. The elves are of the air, and have been more widely received in the faith and poetry of Europe under this name than under that of sylphs, invented by Paracelsus. They are capricious spirits, of diminutive size but preternatural power. Their stature is less than the size of a young girl's thumb, yet their limbs are most delicately formed, and when they will they can hurl granite blocks, bind the strongest man, or shake a house. They are divided in the sagas into good and bad, or light and dark elves, the former having eyes like the stars, countenances brighter than the sun, and golden yellow hair, the latter being blacker than pitch, and fearfully dangerous. The elves ordinarily wear glass shoes, and a cap with a little bell hanging from it. Whoever finds one of these slippers or bells

may obtain from the elf who has lost it any thing which he asks for. In the winter they retire to the depths of mountains, where they live in much the same way as men, and in the first days of spring issue from their grottoes, run along the sides of hills, and swing upon the branches of the trees. In the morning they sleep in blossoms or watch the people who pass by, but at the evening twilight they meet together in the fields, join hands, and sing and dance by the light of the moon. They are generally invisible, but children born on Sunday can see them, and the elves may extend the privilege to whomsoever they please. In England and Scotland they became fairies in the former, and brownies in the latter country, and were subject to a king and queen. The islands of Stern and Rugen, in the Baltic, are especially subject to the king of the elves, who rides in a chariot drawn by four black horses, and whose passage from island to island is recognized by the neighing of the steeds, the blackness of the water, and the bustle of the great aerial company who follow in his train. The elves sometimes become domestic servants, and would be valuable as such if they were less easily offended and less dangerous after taking offense. As long as their caprices are gratified, their food and drink regularly left at an appointed place, and no attempt made to interfere with their freedom, the furniture is sure to be dusted, the floor to be swept, and every chamber to be perfectly in order. But the brothers Grimm, in their 'Deutsche Sagen,' have chronicled the misfortunes of many a young girl, who, having called an elf to her aid, repented too late of having offended it.

El'well, Frank Edwin, American sculptor: b. Concord, Mass., 15 June 1858. He studied at the Ecole des Beaux Arts, Paris, and also under Jean Alexandre Falguiere, and is a member of the Institute of France. Among his works are a monument at Edam, Holland, 'Death of Strength'; statue in Paris of 'Awakening of Egypt'; equestrian statue of Gen. Hancock at Gettysburg; monument to Edwin Booth, Mount Auburn, Cambridge; the two fountains of 'Kronos' and 'Ceres' at the Pan-American Exposition, Buffalo; 'Dickens and Little Nell,' Fairmount Park, Philadelphia; and a bust of Levi P. Morton, Senate chamber, Washington.

Elwell, James William, American philanthropist: b. Bath, Me., 27 Aug. 1820; d. Brooklyn, N. Y., 2 Sept. 1899. He became a partner in his father's commission-house in New York in 1838; and after the death of his father founded the firm of James W. Elwell & Company in 1852. The firm owned three lines of vessels to the principal European, southern, West Indian and South American ports. His philanthropic gifts aggregated \$3,000,000, and he bequeathed \$25,000 to his favorite charities. He originated the Helping Hand Society and was one of the founders of the Brooklyn Orphan Asylum. He was also identified as trustee or director with many other charitable institutions.

El'wood, Ind., city in Madison County; on the Pittsburg, C., C. & St. L., and the Lake Erie & W. R.R.'s; about 50 miles northeast of Indianapolis. It is surrounded by an agricultural region, and is in a natural-gas belt. Its industries are chiefly lumber, flour, tin-plate-mills; window, plate glass and lamp chimney

and other factories. Its shipping trade consists in the agricultural products of the surrounding country, and the articles manufactured in the city. Pop. 12,950.

Ely, Richard Theodore, American political economist: b. Ripley, N. Y., 13 April 1854. He was graduated from Columbia University in 1876, and studied also at Heidelberg, Germany. He became professor of political economy at Johns Hopkins University in 1881, and professor of political economy and director of the school of economics and political science at the University of Wisconsin in 1892. On account of his advocacy of trade unions, he was accused in 1894 of "aiding and abetting" a strike, and of being a Socialist, and an attempt was made to force him out of his professorship at the university. A committee of the regents appointed to investigate the matter acquitted him. While he is not a Socialist, he advocates public ownership of "natural monopolies" and has carefully investigated and stated the aims of the Socialist movement. His works include: 'French and German Socialism in Modern Times' (1883); 'Socialism and Social Reform' (1894); 'Recent American Socialism' (Johns Hopkins University Studies, Vol. III., 1885); 'Problems of To-Day' (1886); 'The Labor Movement in America' (1886); 'Political Economy' (1889); 'Social Aspects of Christianity' (1889); 'Social Law of Service' (1900); 'Monopolies and Trusts' (1900). This last is a small part of a large work, 'The Distribution of Wealth,' which is not completed.

Ely, England, an episcopal city, in the county of Cambridge; about 15 miles northeast of Cambridge; on the Ouse. The place is noted for its cathedral, one of the most remarkable edifices of the kind in England. It occupies the site of a monastery founded about the year 673 by Saint Etheldreda (or Audry), daughter of Anna, king of East Anglia. Its ancient history is most interesting. In 1071, Hereward, the noted English outlaw, defended Ely against the Normans. See HEREWARD. Pop. 7,812. Consult: Van Rensselaer, 'English Cathedrals'; F. Bond, 'English Cathedrals'; Stewart, 'Architectural History of Ely Cathedral.'

Ely, Isle of, a district in England, in the county of Cambridge, separated on the south by the Ouse from the remaining portion of the county, and forming itself a sort of county; area 227,326 acres. It rises about 100 feet above the general level of the fen country, and was formerly surrounded by marshes, which at times became sheets of water. The whole has by drainage been converted into fertile fields. Pop. (1901) 64,494.

Elymais, ʔl-ʔmā'is. See ELAM.

Elyot, ʔl'ʔ-ʔt, **Sir Thomas**, English author: b. Wiltshire not later than 1490; d. Carlton, Cambridgeshire, 20 March 1546. In 1511 he became clerk of assize, in 1523 clerk of the king's council. In 1531-2, as ambassador to Charles V., he visited the Low Countries and Germany, having orders to procure, if possible, the arrest of Tyndale. 'The Boke named the Gouernour, devised by Sir Thomas Elyot, Knight,' was published in 1531. It may be described as the earliest treatise on moral philosophy in the English language, the author's principal object being "to instruct men in such vertues as shall

be expedient for them which shall have authority in a weale publike." An elaborate 10th edition appeared in 1880, with life notes and glossary by H. H. S. Croft. Elyot's 12 other works include: 'Of the Knowledge which maketh a Wise Man' (1533); 'Pasquil the Playne' (1533); 'Isocrates' 'Doctrinal of Princes' (1534); 'Picus de Mirandola's 'Rules of a Christian Lyfe' (1534); 'The Castel of Helth' (1534); 'The Bankette of Sapience' (1534); 'Bibliotheca' (1538), the first Latin-English dictionary; 'The Image of Governance' (1540); 'Defence of Good Women' (1545); and 'Preservative against Deth' (1545). These books went through edition after edition in their author's lifetime, and have now become among the rarest treasures of the bibliomaniac.

Elyria, Ohio, city, county-seat of Lorain County; on the Black River; and on the Cleveland, L. & W., and the Lake Shore & M. S. R.R.'s; 25 miles southwest of Cleveland. Agriculture is the chief industry of the surrounding country; the sandstone quarries furnish employment to a number of people. The chief manufactures in the city are supplies for automobiles and bicycles, saddles, and iron and steel products. Pop. 8,112.

Elysée, Palais de l', pǎ-lâ dê lâ-lê-zâ, the official residence of the president of France, in Paris, on the Rue du Fauburg St. Honore, with its garden extending to the Champs Elysees. It was built in 1718 for the Count d'Evreux; in the reign of Louis XV. it became state property, and was the residence of Madame de Pompadour. It was also used as a residence by Napoleon I., and by Louis Napoleon, and became the presidential residence in 1871.

Elysian Fields, or Elysium, in classical mythology, the residence of the blessed after death. Elysium was supposed by Homer to have been at the western end of the earth; other poets placed it in the Fortunate Isles; later it was supposed to be in the under world. It was represented as a region of perfect happiness, where the sky was always cloudless, and a celestial light shed a magic brilliancy over every object; where each one was free to follow his favorite pursuit, and cares and infirmities were unknown.

Elze, ěl'tsě, Karl, German historian of literature: b. Dessau 22 May 1821; d. Halle 22 Jan. 1889. His specialty was English literature, and he was professor of English philology in the University of Halle 1875-89. One of his first works was a compilation entitled a 'Treasury of English Song.' He produced critical editions of Shakespeare and other English dramatists, and wrote biographies of Byron and other English authors. Specially noteworthy is his 'Outline of English Philology.' 'Westward' (1860) contains translations of English and American poems.

Elzevir, ěl'zě vřr, name of a notable family of printers descended from Ludovic Elsevier or Elzevier, Latinized Elzevierius, a native of Louvain: b. 1540. Having learned the bookbinders' trade, he practised it for some years in his native town, but 1580 he removed to Leyden in the United Provinces, and there set up a printing press. His five sons, Matthew, Ludovic, Egidy, Joost, and Bonaventura, were also printers and booksellers; but it was the youngest of the five, Bonaventura, born 1583 at Leyden,

that gave the name Elzevir its great celebrity. The first work published by the house of Elzevir appeared in 1583, the 'Ebraicæ Quæstiones et Responsiones' of Drusius, not the whole three books, but only the second and third. In 1608, nine years before his father's death, Bonaventura Elzevir founded a separate printing and publishing establishment in the same city, and then commenced the issue of works in Greek, Latin, and other languages which have ever since been regarded as models of correct and elegant typography. He conducted the business of his house more than 42 years, till his death in 1652, having had as partner from 1626 Abraham Elzevir, his nephew, whom he survived one month. He was succeeded by his son Daniel and Abraham's son John: this partnership was soon dissolved, John carrying on the business in Leyden, Daniel migrating to Amsterdam in 1655 and entering into partnership there with another of his cousins: both of these were dead 1680. The last of the Elzevirs to figure in the history of typography was Abraham, son of Abraham, one of the five sons of Ludovicus: from 1681 to 1712 he was printer to the University of Leyden. The Elzevir editions of the ancient classics, especially Latin, while admirable in point of typography, are mostly reproductions of the texts adopted by previous printers and hence are inferior from the critical point of view. The number of works published by the different Elzevir houses number 1,213, namely, Latin 968; Greek 44; French 126; Flemish 32; Oriental 22; German 11; Italian 10.

Emancipation, the act by which freedom of various kinds is granted to individuals, races, or nations. In Roman law the dissolution of paternal authority (*patria potestas*) in the lifetime of the father. It took place in the form of a sale by the father of the son to a third party, who manumitted him. The Twelve Tables, the foundation of Roman law, required that this ceremony should be gone through three times. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a patron which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren one sale was sufficient. The Catholic Emancipation Act was the act signed 13 April 1829, which removed the most galling of the Roman Catholic disabilities in England. See CATHOLIC EMANCIPATION; EMANCIPATION PROCLAMATION; SLAVERY.

Emancipation, Catholic, the customary designation of a measure of relief from penalties and civil disabilities granted to professors of the Catholic religion in England and Ireland by acts of the British Parliament 1829: the act did not extend to Scotland. The necessity of granting relief to the Catholics of Ireland became apparent soon after the outbreak of the war against the American colonies, and the first relaxation of the penal laws against the professors of the Catholic religion was made in 1780. At that time it was high treason for a priest, native of the kingdom, to perform any of the duties of his office. Catholics could not own land in fee. Roman Catholics whose titles to land antedated the penal laws were ousted if the legal heir professed Protestantism. A Catholic could not practise law, nor conduct a school. In 1780 a bill for removal of some of the disabilities was

EMANCIPATION IN LATIN-AMERICA

passed for England and Ireland. When the act of union of the kingdom of Ireland with that of Great Britain was passed in the Irish Parliament 1800, solemn pledges were given by the British Cabinet that the disqualifying statutes should be repealed; but after the union the promise was ignored. In 1824 in Ireland was formed the Catholic Association to agitate for civil rights, such as the right to vote for members of the Parliament, to be elected members of the same, and to occupy various offices in the government, national and local. In 1829 it was seen by English statesmen that to withhold these rights and franchises any longer would provoke a rebellion in Ireland; and a bill of relief was introduced in the Parliament 5 March, and passed in both houses and approved by King George IV. 13 April, permitting Catholics to elect and be elected to the Parliament, and to hold offices under the Crown; but they remained still expressly excluded from certain high offices—that of lieutenant-governor of Ireland, that of regent of the universal kingdom, of lord chancellor of the United Kingdom, or of Ireland, etc. In 1867 the last named disability was removed, as was, many years after, the disability of a Catholic to be lord chancellor of the United Kingdom. But the Act of Grace of 1829 contained a clause forbidding Catholic ecclesiastics, monks, friars, and nuns from wearing the attire or habit of their respective station or order in public under a penalty of \$250 for each offense. This proviso was ostentatiously violated in Ireland, and with impunity, for, like the \$500 forfeiture for violation of the Ecclesiastical Titles Acts (q.v.), no penalty was ever exacted. Another clause of the Catholic Emancipation Act, which was also ignored and condemned, required that Jesuits and members of religious orders of the Roman Catholic Church living within the kingdom should register in the office of the clerk of the peace of the county under a penalty of \$250. See O'CONNELL, DANIEL. Consult: Butler, 'Historical Memoirs'; Milner, 'Supplementary Memoirs'; Lingard, 'History of the Church in England'; Green, 'History of England.'

Emancipation in Latin-America: the Manumission of Slaves in Relation to the several Declarations of Independence. In Haiti, where African slavery was first introduced into America, the negroes received as a gift "the full liberty, equality, and fraternity" of the French republic in 1794, and by fighting established their independence in 1804. In Central America (when Guatemala, Salvador, Honduras, Nicaragua, and Costa Rica were united in the Central American republic), the laws of 31 Dec. 1823 and 17 and 24 April 1824 emancipated all slaves, and made free slaves of other countries coming to Central America. The slave trade was prohibited, under penalty of forfeiture of the rights of citizenship. H. H. Bancroft, in his 'History of the Pacific States,' says: "Of all the nations of North America, to the Central American republic belongs the honor of having first practically abolished slavery." We shall presently show, however, that this distinction fairly belongs to Mexico. Ecuador, which made its first effort to gain independence at Quito, 10 Aug. 1809, and actually threw off the yoke of Spain on 9 Oct. 1820, abolished slavery during the presidential term of Gen. Urvina, 1852-6. The Argentine nation began its struggle for independence 25

May 1810, and at the congress of Tucuman, 9 July 1816, the formal separation from Spain was declared. Article XV. of the Constitution of 25 Sept. 1860 provides that "there shall be no slaves in the Argentine nation. Those few who now exist in it shall become free at the very moment this constitution goes into effect. The indemnifications which this declaration may involve shall be provided for by special law. Any contract involving the purchase or sale of a person shall be held to be a criminal offense. . . . Slaves introduced in any way whatever into the country shall become free by virtue of the fact that they have trodden the soil of the republic." In Colombia (New Granada) the number of negroes was never very great; it was estimated at 80,000 in the middle of the 19th century. The struggle for independence, beginning 20 July 1810, or as a vigorous insurrection in 1811, was continued after the union with Venezuela (December 1819), and the republic of New Granada was formed in 1831. In 1821 a law was passed by the republic of Colombia for the gradual manumission of slaves, and all born after that date were declared free at the age of 18,—that gradual process applying, of course, to all the territory of the Greater Colombia at the time of the law's enactment. (See *COLOMBIA, History*.) A law of 1851 abolished slavery entirely in New Granada, by giving liberty to all who remained slaves on 1 Jan. 1852, provision being made for the payment of indemnity to the owners. The beginning of the war for independence in Mexico dates from 16 Sept. 1810 (see *DOLORES, EL GRITO DE*); on 6 Nov. 1813 the first Mexican congress, installed in the town of Chilpancingo, issued the declaration of independence and decreed the emancipation of slaves. This, therefore, was the starting point of emancipation on the mainland of America. Venezuela's declaration of independence (5 July 1811) was followed after 10 years by the law for the gradual manumission of slaves which we have mentioned above, that is, the law of the Greater Colombia of 1821. Paraguayan independence should be dated from 11 June 1811, when an assembly of deputies began its sessions; for the resolution passed by this assembly, renouncing allegiance to Spain, was ratified as a declaration of independence by the Paraguayan congress of 1 Oct. 1813. The question of African slavery was comparatively unimportant in Paraguay. "In 1865 there were negroes and mulattoes at Emboscada, Tabapy, and Aregui; but the negroes have now almost completely disappeared" ('Handbook of Paraguay,' September 1902, issued by International Bureau of the American Republics). Chile entered upon a contest with Spain on 18 Sept. 1810, and the independence of the country was proclaimed 12 Feb. 1818. The negro problem did not weigh upon that country, the population being recruited from Europe quite largely. The independence of Peru was declared at Lima 28 July 1821; that of the Dominican republic 1 Dec. 1821; that of Brazil 7 Sept. 1822; and Bolivia became an independent republic 6 Aug. 1825. In Brazil the conservative statesman, Silva Paranhos, obtained from the parliament the passage of a bill (28 Sept. 1871) for the gradual extinction of slavery, which provided that thereafter every child born of a slave mother should be free, and created a special fund for emanci-

EMANCIPATION PROCLAMATION

pation by redemption. Private philanthropy, largely directed by the Masonic lodges, effected more than the fund created for this purpose; and the number of slaves began to decrease. A bill for the immediate and unconditional abolition of slavery in Brazil was signed by Princess Regent Isabel 13 May 1888; the monarchy was overthrown 15 Nov. 1889; the new Constitution approved 24 Feb. 1891. In Cuba the slaves were emancipated on the conclusion of the Ten Years' War, that is, in 1878, and Cuba became a republic 20 May 1902. The experiences of the French, Danish, and British possessions may be referred to briefly in conclusion. Napoleon restored slavery in French Guiana, Martinique, and Guadeloupe, although his efforts to accomplish the same result in Haiti were, as mentioned above, frustrated by the resistance of the blacks themselves. The freedom of all who were held in bondage throughout the French dominions was declared in 1848. Slavery in the Danish West Indies (St. Thomas, etc.) was abolished also in 1848. The act to abolish slavery throughout the British colonies, providing £20,000,000 for compensation of the owners, was dated 28 Aug. 1833, and its effect was to free 770,280 slaves on 1 Aug. 1834, the number thus emancipated in Jamaica being 309,000.

MARRION WILCOX.

Emancipation Proclamation, 1 Jan. 1863. The Republican administration at the outbreak of the Civil War was awkwardly placed for dealing with slavery. To assail it in its own territory was not only to belie the past professions of the party, but to alienate so much Northern support as to assure failure; nor indeed had the great bulk of the party any thought beyond fettering the slave power for future aggression. On the other hand, to leave slavery untouched was not only to chill the energies of the most reliable upholders of the War, but to give foreign countries a pretext for asserting that the North was fighting merely for dominion, and that the Southern cause was that of liberty and morally entitled to help. The former horn of the dilemma was much the sharpest; and the government moved very cautiously, restraining its subordinates like Fremont (30 Aug. 1861) and Hunter (9 May 1862) from forcing its hand by emancipation orders. On 9 Aug. 1861 an act had declared masters employing slaves against the government barred from further claim to them; but that was a mere warning and rule of court. The first embarrassing problem was how to deal with slaves in conquered districts, or who had come within its lines: was the government to act as slaveholders' trustee and return them to servitude? The growing resentment against slavery as a convertible term for the rebellion, and disgust at being slave-catchers to the behoof of their enemies, supplied the answer, and on 13 March 1862 all army officers were forbidden to return fugitive slaves; their surrender from any quarter was made harder (though the fugitive-slave law was not formally abolished till 28 June 1864); on 17 June 1862 all captured, deserted, or fugitive slaves of owners in rebellion were freed. As to the main body, who plainly could not be left in unchanged status as the core of a fresh abscess, Lincoln's wish was for compensated emancipation; he sent a special message to Congress 6 March, and that body passed a joint resolution 10 April, declar-

ing that the United States ought to co-operate with any State which would adopt gradual abolition, by paying for the slaves, and on 16 April those in the District of Columbia were thus emancipated; but despite his repeated urgencies, the border States would take no measures of the kind. On 19 June the slaves in the Territories were freed.

The final blow came, as John Quincy Adams 20 years before had forecast that it would, by using the President's war power to suppress insurrection. As the second year of the conflict wore on, the majority demanded the crippling of its enemy by the most efficient means, and very many believed that a threat of general emancipation would bring about a general surrender. Lincoln wished for a great victory first, that it might not appear the selfish resource of an over-matched power; but the discouraging Peninsular campaign obliged him to satisfy his supporters by holding this bludgeon over the enemy. On 22 Sept. 1862 he issued a proclamation announcing that 100 days after, on 1 Jan. 1863, the Executive would issue another proclamation designating the States or parts of States then deemed in rebellion, evidence to the contrary being the presence of *bona fide* representatives in Congress, that all slaves in the designated sections should be permanently free, and that the civil and military authorities of the United States would maintain their freedom, and would not repress any effort of theirs to make it good. The only result was a retaliatory proclamation by Jefferson Davis 23 December, ordering that captured negro Federal soldiers and their officers should be turned over to the States, and that Gen. B. F. Butler should be hanged if captured. On the 1st of January the threatened proclamation was issued, as "by virtue of the power in me vested as commander-in-chief of the army and navy of the United States, and as a fit and necessary war measure for repressing said rebellion." It designated Arkansas, Texas, Louisiana except 13 "parishes" or counties, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia except West Virginia and seven other counties, as in rebellion, emancipated all the slaves in them; enjoined these freedmen to abstain from all violence except in self-defense, and to work faithfully for reasonable wages; announced that suitable members of them would be received into United States military and naval service, and for this act invoked "the considerate judgment of mankind and the gracious favor of Almighty God."

The curious feature of this proclamation is that it abolished slavery only in the sections not under the military power of the United States, and left it untouched in those which were, namely, the ones specially excepted by it, "which are, for the present, left precisely as if this proclamation were not issued." Hence it was argued by the Democrats that it had no legal force whatever, and emancipated no one; a question the Supreme Court never passed on. It was always accepted by the majority party, however, as a continuing act, applying as fast as any of that territory fell into the Union power, and not necessary to repeat. Politically, the results were enormous. Recognition of the Confederacy thenceforward meaning a flat maintenance of slavery instead of freedom, the entire anti-slavery sentiment of France and Great Britain was thrown against those countries' interference, which at once be-

FROM THE PAINTING BY CARPENTER.

SIGNING THE EMANCIPATION PROCLAMATION.

EMANTS — EMBANKMENT

came unthinkable. It drove away many lukewarm northern Republicans, and brought many local and State defeats to the administration; but it took the party "off the fence," and made it a coherent organization with one firm, open principle, for many years unassailable. In the South, as defeat meant emancipation by their enemies and it would be no worse if done by themselves, some of the leaders (as Lee) seriously thought of offering freedom to slaves to fight in their armies in the latter part of the War, hoping to save independence and the control of their own destinies at least.

Emants, ěm'ants, **Marcellus**, Dutch poet and descriptive writer: b. Voorburg, near The Hague, 12 Aug. 1848. His volumes of travels display his keen observation and his poetical imagination. Among his best are: 'A Journey Through Sweden' (1877); 'Monaco' (1878); 'Along the Nile' (1884); 'From Spain' (1886). He holds a permanent place in the literature of the Low Countries through his charming narrative poems, 'Lilith' (1879); 'The Shimmer of the Gods' (1883).

Eman'uel the Great, king of Portugal: b. 31 May 1469; d. Lisbon 13 Dec. 1521. He ascended the throne in 1495. During his reign were performed the voyages of discovery of Vasco da Gama, of Cabral, of Americus Vesputius, and the heroic exploits of Albuquerque, by whose exertions a passage was found to the East Indies (for which the way was prepared by the discovery of the Cape of Good Hope in 1486 by Bartolomeo Dias), the Portuguese dominion in Goa was established, the Brazils, the Moluccas, etc., were discovered. The commerce of Portugal, under Emanuel, was more prosperous than at any former period. The treasures of America flowed into Lisbon, and the reign of Emanuel was justly called "the golden age of Portugal." He died deeply lamented by his subjects, but hated by the Moors and the Jews, whom he had expelled. As a monument of his discoveries, Emanuel built the monastery at Belem, where he was buried. He was a friend to the sciences, and to learned men. He left 'Memoirs on the Indies.'

Emba, ěm'bā, a river in the district of Orenburg, Asiatic Russia; the Russians call it Jemba, the Kirghiz, Dchem. It rises at three sources in the western slope of the Mugodchar foothills; flows sluggishly through an area of steppes, is about 200 feet wide and 500 miles long, and forms a delta at its embouchure in the Caspian. It is not navigable, but abounds in fish. The fortress Embinsk is built on its upper waters.

Embalming, the act of preserving the body after death. It was probably invented by the Egyptians, whose bodies thus prepared for preservation are known as mummies, but it also prevailed among the Assyrians, Scythians and Persians. It is at least as old as 4000 B.C. The Egyptian mummies were placed in costly coffins ready for sepulture; but were frequently kept some time before being buried—often at home—and even produced at entertainments, to recall to the guests the transient lot of humanity. The usual method of embalming among the ancients was as follows: The intestines and brains were taken out, and the cavities filled up with a mixture of balsamic herbs, myrrh, etc.; the arteries and other vessels were injected with balsams.

The ancient Egyptians filled the cavities of the trunk with aromatic, saline, and bituminous stuff. The cloths in which the mummies were swathed were saturated with similar substances. So effectual were some of the processes that, after 2,000 or 3,000 years, the soles of the feet are still elastic and soft to the touch. By 700 A.D., when embalming practically ceased in Egypt, probably 730,000,000 bodies had been thus treated; many millions of them are still concealed. In 1881 upward of 30 mummies of potentates, including that of Rameses II., were discovered together at Deir-el-Bahari. (See MUMMY.) The Persians employed wax for embalming; the Assyrians, honey; the Jews aloes and spices. Alexander the Great was preserved in wax and honey. Desiccated bodies, preserved by atmospheric or other influence for centuries, have been found in France, Sicily, England, and America, especially in Central America and Peru. The art of embalming was probably never wholly lost in Europe. The body of Edward I., buried in Westminster Abbey in 1307, was found entire in 1770. The body of Canute, who died in 1036, was found very fresh in Winchester Cathedral in 1776. The bodies of William the Conqueror and of Matilda, his wife, were found entire at Caen in the 16th century.

Chaussier's discovery, in 1800, of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard and grayish, introduced new means of embalming; but, owing to the desiccation, the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Gannal, in 1834, and of arsenic by Tranchini, pyroxilic spirits by Babington and Rees in 1839, and of the antiseptic nature of chloride of zinc, have led to the application of these salts to the embalming of bodies required to be preserved for a limited time. The latest method common in the United States is an injection of a fluid into the femoral artery and the cavity of the abdomen. The most efficient agents are mercuric chloride, arsenic and zinc chloride.

ROGER S. TRACY, M. D.,
Health Department, New York City.

Embankment, a mound of earth, thrown up either for the purpose of forming a roadway at a level different from that of the natural surface of the ground, or for keeping a large body of water within certain limits. The slopes should be adapted to the material, so as to secure permanence. To prevent subsidence on marshy or peaty soils, either the weight of the heart of the embankment is diminished, as in Holland, by introducing layers of reeds, or fascines, or artificial foundations are prepared. The embankment may be prevented from slipping laterally by forming steps in the earth of the subsoil, or by cutting deep trenches at the feet of the slopes. In cases where embankments are raised for the storage of water, a "puddle-dike," that is, a water-tight wall, must be inserted through the whole depth of the bank down to the impermeable strata beneath. To resist the action of wind and rain, or of the waters of a slow-flowing stream, the banks should in all possible cases be covered with turf. When embankments are raised at right angles to the current of a river they are called dams.

EMBARGO — EMBER-DAYS

When they run parallel to the current, and prevent its lateral overflow they are styled levees. Among the largest embankments hitherto executed are those on the banks of the Po, the Meuse, the Scheldt, the Mississippi, United States, on the shores of the Netherlands, and the Croton dam at the head of the reservoir for the supply of water to New York, the Oberhäuser embankment on the Augsburg & Lindau Railway, the Gadelbach cutting on the Ulm & Augsburg Line, and the Tring cutting on the North-western Railway (England). See **LEVEES**; **RESERVOIRS**.

Embargo in the United States. Prohibition of foreign commerce, to distress foreign countries and obtain the revocation of hostile measures; "peaceful war," intended to be cheaper than actual warfare and equally efficient, but in fact injuring ourselves deeply and the others little, and ending in real war at last. Our embargos belong exclusively to the French-English wars of 1794-1814. Their ultimate cause was that the agricultural classes, who controlled the administration, did not believe in commerce, and preferred abolishing it to spending anything for its protection; moreover, they were mainly southern and democratic, the commercial interests mainly New England and Federalist, and the former were not loth to spare themselves the cost of war by impoverishing the latter. The first embargo was for 60 days, due to mutual orders of France and England for seizure of neutrals which placed the United States between hammer and anvil. Jay's Treaty (q.v.) of 19 Nov. 1794, for 12 years measurably protected our commerce, but near its end conditions became infinitely worse. In 1806-7 the thronging mutual blows of England and Napoleon, ending in the former's Orders in Council of 11 November, and the latter's Milan Decree of 7 Dec. 1807, made practically every neutral vessel good prize to one or the other. Even more intolerable were the rights of search and impressment claimed by Great Britain, which swept several hundred American sailors every year into the British fleets, and in one massacre (see **CHESAPEAKE AND LEOPARD**) outraged and humiliated this country beyond forgiveness. But aside from the reasons above given, few landsmen believed till the victory of Old Ironsides (see **CONSTITUTION**, **THE**) that American ships could fight English on equal terms, and it was the general conviction that in case of war our entire fleet would at once be "Copenhagened" (that is, captured bodily and added to the British fleet, as was the Danish). At Jefferson's recommendation, therefore, "The Embargo" was passed 22 Dec. 1807, forbidding all foreign commerce till the obnoxious decrees were repealed. The havoc not only in trade but in the interior life of the people was terrific: the exports fell from \$110,084,207 in 1807 to \$22,430,960 in 1808. The farming sections were dismayed to find that commerce meant part of their daily bread as well as the carriers' profits, and that they raised and sold much of that \$87,000,000; but they clung all the more stubbornly to their anti-war recipe, though England and France approved it highly. Napoleon was glad to see his enemy drifting into war with a western power; England was glad to regain her carrying trade, and see Canada and Nova Scotia receive American capital. Meantime New England fought it with the fierceness of a struggle for life; evaded it largely by sea, and

sent armies of smugglers overland to Canada. Congress then extended the act to rivers, lakes, and bays, and allowed collectors to seize on suspicion; and the next Congress, 9 Jan. 1809, passed a savage enforcing act with all the fury of baffled doctrinaires, imposing enormous fines, forfeitures, and bonds, and making the collectors supreme despots of their districts. New England was nearly in insurrection; the collectors were in danger of the fate of those under the Stamp Act, some resigned, others were sued in the State courts; the judges would give no findings against smugglers; finally the States threatened nullification, and John Quincy Adams (a victim to its support) declared that they had resolved to withdraw from the Union, at least temporarily, if force were used, and had opened negotiations with Great Britain. A Federalist declared in the Senate that blood would flow. The Democrats were frightened, and hastily fixed (3 Feb. 1809) 4 March for its discontinuance. But the next month they had regained courage, and passed a "non-intercourse act" to take its place; still prohibiting intercourse with France or Great Britain, but restoring it with other countries and allowing free coasting trade. This policy was continued till the War of 1812 opened. The hostility of New England to the war, only less destructive than the embargo and against her political feelings, induced the British government ostentatiously to relieve that section from the blockade, to sow discord and make a base of naval supplies; and on 17 Dec. 1813 a new embargo was laid to 1 Jan. 1815, which, however, was repealed 14 April 1814. Jefferson always asserted that the policy was the best, and the embargo would have accomplished its object if New England would only have helped. (Histories of the United States through this period, as Schouler, McMaster, etc.; especially Henry Adams' 'History,' covering 1801-15, devoted to the causes and consequences of these measures.

Em'bassy (*ambassy*, from O. Fr. *ambassée*, from low Lat. *ambachus*, a servant, vassal) in its strict sense, signifies a mission presided over by an ambassador, that is, a diplomatic agent of the first rank, as distinguished from a legation or mission entrusted to an envoy or agent. The difference between the powers and privileges of an ambassador and an envoy is, that the former, as the representative of the person of his sovereign, can demand a private audience of the sovereign to whom he is accredited, while the latter must communicate with the minister for foreign affairs. See **DIPLOMACY**.

Ember-days, called in the Roman Missal and Breviary *Quattuor Tempora* (the four seasons) and in the Anglican 'Book of Common Prayer' "Ember-days at the four seasons," are in the Roman and in the Anglican calendar the Wednesdays, Fridays, and Saturdays which come next after 13 December, the first Sunday of Lent, the Feast of Pentecost (Whitsunday), and 14 September, respectively. In both the Latin Church and the Anglican these days are days of fasting. The *Quattuor Tempora* were observed at Rome in the time of St. Augustine (the bishop of Hippo, early in the 5th century), and doubtless the observance was already of ancient date. The custom was brought into Britain by that other St. Augustine who was the herald of the gospel to the Anglo-Saxons. It was anciently the custom for bishops to hold

ordinations only on the Saturdays of the *Quatuor Tempora*. The origin of the phrase Embur-days cannot be definitely ascertained: but it is probably a corruption of *Quatuor Tempora*, as in German *Die Quatember* signifies the Embur-weeks.

Ember, or **Immer Goose**, the name in northern Scotland of the loon (q.v.).

Embezzlement (O. Fr. *besiler*, to rifle, lay waste) is the appropriation, by a clerk or servant, of money or property put into his hands for trust. Embezzlement is both a theft and a breach of trust; yet, by the general law, it is only a ground for an action for the value of the property. It must not be confounded with larceny, which is "the felonious taking and carrying away the personal property of another." This "taking" implies a trespass, not to be chargeable in embezzlement, which is an offense or form of crime invented by the English statute, which the United States copied and which changed what was not larcenous into a punishable crime, being the act of fraudulently appropriating to personal use money or property held under a fiduciary relation. This crime in the United States is very severely punished as a felony.

Em'blements (O. Fr. *emblacement*, from *emblaer*, to sow with grain), a term applied to the growing crops of land when the lease of a tenant for life has expired by the death of the tenant, or when an estate at will has been determined by the lessor. In either case the emblements belong to the tenant or his executors. But when the tenant puts an end to his occupation by his own voluntary act, he will not be entitled to the crops.

Embolism, *ēm'bō-līzm* (Gr. *εμβολισμος*, intercalation, *ev*, in, and *βάλλειν*, to cast). In the calendar, an intercalation of a day, as in the second month of our year in leap-year, or of a lunar month, 28 days, in the Greek calendar. In medicine, the blocking up of a blood-vessel by a clot of blood that comes from some distance till it reaches a vessel too small to permit its onward progress. This is often the cause of sudden paralysis and death, or of gangrene and pyæmia.

Embos'sing (Fr. *bosse*, a protuberance), the art of producing raised figures upon plane surfaces, such as on leather for bookbinding, etc.; on paper, wood, or bronze. In architecture or sculpture, in proportion as the figures are more or less prominent, they are said to be in *alto*, *mezzo*, or *basso rilievo* (high, half, or low relief). Leather, paper, and textile fabrics are embossed by powerful presses furnished with dies of the desired pattern.

Embra'cery (O. Fr. *embraser*, to set on fire), an attempt to corrupt or influence a jury by money, promises, letters, threats, or persuasions. This offense in the United States is punished by fine and imprisonment.

Embrasure, *ēm-brā'zūr*, in fortification, an opening made in the breastwork or parapet of a battery or fortress, to admit of a gun being fired through it. See **FORTIFICATION**.

Embree, **Charles Fleming**, American author: b. Princeton, Ind., 1 Oct. 1874. He is the author of 'For Love of Tonita' (1897); and 'A Dream of a Throne' (1900); 'Heart of Flame.'

Embro, a corrupted form of the name Edinburgh. See **EDINBURGH**.

Embroidery, the art of producing ornamental patterns by means of needlework on textile fabrics, leather, and other materials. It is closely allied to tapestry, from which, however, it must be distinguished. The essential distinction is that in tapestry work the basis is a series of parallel strings, forming a warp, and the patterns are produced by the manipulation of the threads which form the weft, while embroidery is always worked on an already complete fabric.

The art of embroidery is practised, with characteristic variations, by the rudest tribes, and was well known in very early times. Remains of Egyptian embroidery as ancient as the days of Jacob exist still; and the costumes painted on the monuments of the 18th dynasty show that the most varied patterns were used by the Egyptians 3,000 years ago. The Jews probably acquired the art in Egypt; the description of the curtains of the tabernacle and the garments of Aaron (Exodus xxvi., 1-31, and xxxix.) and other allusions in the Scriptures indicate that their skill in the art was considerable. The knowledge of artistic embroidery came to Europe from the East, where it had its early home, and where it is still most largely practised. To the Greeks and Romans it came from Phrygia, whence at Rome the embroiderer was known as *phrygio*, and embroidered work was called *phrygium*. Frequent references to embroidery are found in Homer, and all later classical writers. It was in mediæval times that the embroiderer's art attained its greatest perfection in Europe, and embroidery was a favorite occupation of women of all ranks. Not only was figure and portrait embroidery highly developed, but, in France especially, much attention was paid to the use of floral and arabesque ornament. Much of the most beautiful mediæval work is found on the vestments and ornaments for the monasteries and churches. Among other famous specimens are two of English origin, the Syon cope of the 13th century, richly charged with scriptural subjects, and the Bayeux Tapestry (q.v.), an example of embroidery with worsteds.

At the present day the Orient stands foremost in art embroidery. The Chinese work is perhaps the most elaborate, done mostly on silk, with brilliant colors; the Japanese embroidery is scarcely less beautiful and elaborate. In Europe and America, there has been in the 19th century a revival of the art of embroidery connected with the increased desire for all forms of decorative art. Practically, embroidery is divided into two distinct classes of work: (1) that which embraces all kinds of artistic needlework done by the hand; and (2) the manufacturing industry which includes all embroidery done by machinery, and hand needlework done on the large scale by following patterns mechanically impressed on the fabric. In art embroidery the materials employed are fine colored worsted yarns called crewels, tapestry wools, embroidery silks, gold and silver threads, span-gles, and plates or disks of metal. The textile basis may be any cloth, but the fabrics principally used are stout makes of linen, silks, satins, velvets, and flannels. Small work is done without any special mounting, but for elaborate designs the fabric is fitted and tightly stretched on a

frame. The number of embroidery stitches is considerable, and they vary with the nature of the design and the materials used. The principal stitches are the cross stitch, the cushion stitch, the crewel stitch, the outline stitch, the herring-bone stitch, the button-hole stitch, the feather stitch, the satin stitch (the best for fine work on silk and satin), and the rope and knot stitches. In frame-work, "couching" is largely employed, which consists in laying lengths of thread on the surface, and securing them by stitches through the cloth brought up at various points. A distinct class of embroidery consists of appliqué or cut work, in which designs of different materials and colors are cut out and sewed down on the surface of the fabric to be ornamented. In its purely mechanical side, the embroidery trade embraces several distinct sections, of which may be enumerated: (1) white embroidery, known also as Swiss or Scotch sewed work; (2) embroidery in gold, silver, and colored silks, for official costumes, civil and military, badges, etc.; and (3) embroidery in crewels, or other colored wools, colored silks, etc., mostly done for furniture decoration, such as borders of table covers. To a great extent these various kinds of embroidery can be worked by one or other of the machines which have been devised for embroidering. The first successful embroidery machine was that invented by M. Josué Heilmann, of Mülhausen, patented in England in 1829. With Heilmann's machine, or the modifications of it which have since been introduced, one person can guide from 80 to 140 needles working simultaneously, and producing so many repeats of the same design. Embroidery patterns, in a variety of knotted, tambour, and other stitches, and ornamental braiding, are now very largely done by means of the Bonnaz machine, the invention of M. Antoine Bonnaz, first patented in England in 1868.

Bibliography.—Day and Buckle, 'Art in Needlework' (1900); Higgin, 'Handbook of Embroidery'; Lefèvre, 'Embroidery and Lace' (Eng. trans. 1888); Morris, 'Decorative Needlework'; Palliser (Mrs. Bury), 'Lace and Embroidery.'

Embrun, òn-brùn (ancient *Eburodunum Caturigum*), France; town in the department of Hautes-Alpes, on a rocky eminence in the centre of a large plain watered by the Durance, 20 miles east from Gap. It is an ancient place, surrounded by walls and ditches, and of very picturesque appearance. It was pillaged successively by Vandals, Huns, and Saxons, and its inhabitants almost exterminated by the Moors in 966. It is still a bishop's, and was once an archbishop's, see. Pop. 3,812.

Embryo. See EMBRYOLOGY.

Embryology (ἐμβρυον, a young animal + λόγος, discourse), strictly speaking, is that division of biological science which deals with the structure and growth of the embryo, that is, the young before it is capable of leaving the egg membranes and leading an independent existence. But such limits are inconvenient and the term as usually employed treats of the larval history as well, including all phases of growth until practically the adult form, if not size, is reached.

The account of embryology begins with the egg or ovum. This is a specialized cell (see CELL) formed in the reproductive glands (ovaries) of the mother and differs from all other cells of the body in its capacity, under the proper

conditions, of reproducing an animal like the parent. The eggs of different animals vary greatly in size and appearance. In the simplest condition, as in the starfish and sea-urchin, the egg is a spherical mass of protoplasm (q.v.), with a central specialized portion, the nucleus, all being transparent and having a diameter of about one two hundredths of an inch. From this all variations in size and structure can be traced to the complicated and comparatively enormous eggs of birds. These variations are due to secondary features which are added for the protection and nourishment of the growing embryo.

Thus in the familiar hen's egg there is an external calcareous shell, then the double shell membrane enclosing the albumen or "white." Supported in the white is the yolk, which alone arises in the ovary, the other parts being added by the ducts through which the egg passes on its way to the exterior. Hence the yolk alone is the true egg. This owes its large size (compared with the egg of the starfish) to the fact that it contains not only the protoplasm and nucleus of the latter, but also a large amount of food material (food yolk or deutoplasm). On one side of the yolk is a lighter yellow spot (the "tread"), and in this spot are the nucleus and protoplasm, and in it the processes of development begin. All other parts are secondary or adventitious, and it is to the number, character and amount of these that the differences between the eggs of various animals are due.

In the limits of this article only the simplest and most essential features of development can be described; for details the reader must go to special works, but with greater or less modifications the following account will apply to all eggs.

The egg, as it leaves the ovary, is not ready for development. It must become mature. This process of *maturation* is very complex. In a few words it consists of the formation of two small bodies (*polar globules*), which are thrust out of the egg and play no part in its further history. These polar globules carry with them a small amount of protoplasm and three quarters of the essential material (*chromatin*) of the nucleus. This division of the chromatin is peculiar in that with the formation of the first polar globules half of each kind of chromatin is cast off; with the formation of the second half of the kinds of chromatin are lost. In the formation of the male reproductive element, the *spermatozoon*, there is an essentially similar division of the chromatin. Upon these divisions of the chromatin and the subsequent fertilization of the egg next to be described, all modern theories of heredity are based. After the polar globules are formed the remainder of the original nucleus sink back into the egg and form a *female pronucleus*.

After maturation comes fertilization, which consists in the union of a spermatozoon with the egg. The head of the male element penetrates the protoplasm, increases in size, and forms a *male pronucleus*. The two pronuclei unite and thus there is restored to the egg those chromatin elements which were lost in the formation of the second polar globule. It is to be noticed that in eggs which develop parthenogenetically (that is, without fertilization—see PARTHENOGENESIS) the second polar globule is not formed and hence no lost chromatin has to be restored.

EMBRYOLOGY

Excepting parthenogenetic eggs it is only after fertilization that the egg is normally ready to develop and to begin the formation of the embryo. The first step is the division of the single-celled egg into numerous cells, the so-called *segmentation of the egg*. In the simplest eggs these divisions are regular and total, that is, at each division the resulting cells are equal in size and the planes which separate them cut entirely through the egg. With increase in amount of deutoplasm, as in the egg of the frog, there is a difference in the size of the cells, those at one pole being large, those at the other small (*unequal segmentation*). With still further increase in the amount of food yolk, only a part of the egg divides, and we have *partial* or *meroblastic segmentation*, as in the case of sharks, reptiles, and birds. These variations exercise a great influence upon the subsequent history of development, modifying the various processes in ways which are described in embryological text-books. The peculiar *centrolecithal* eggs of crustacea and insects need not be considered here.

In eggs with equal and total segmentation the first division plane cuts the egg into equal halves. The second plane, at right angles to the first, results in quarters. These two planes, from their relation to the meridians of the globe, are termed meridional planes. The third, which is at right angles to the first two, corresponds to the equator and divides the four cells into eight. After this meridional planes and planes parallel to the equator alternate, increasing the cells in geometrical ratio so that we have 2, 4, 8, 16, 32, 64, 128, 256, etc., cells as a result. In unequal segmentation this regularity is soon lost, while in meroblastic eggs the divisions result in a small patch of cells, the *blastoderm*, on one side of the yolk, as in the hen's egg at the time of laying.

At first the cells resulting from this segmentation form a solid mass known as the *morula* (mulberry) stage. Later this becomes a hollow sphere of cells, one layer thick, the so-called *blastula* (Fig. 1 left), its cavity, in contradistinction to other cavities which may appear later in the embryo, being known as the *segmentation cavity* or *blastocæle* (archicæle). In eggs with regular segmentation the wall of the segmentation cavity is composed of equal-sized cells,

FIG. 1.—Diagrammatic sections of blastula (left) and gastrula (right); *a*, archenteron; *bl*, blastopore; *ec*, ectoderm; *en*, entoderm; *sc*, segmentation cavity.

but in unequally segmenting eggs the cells on one side are thicker than those on the other and the segmentation cavity is more or less excentric in position.

Next in sequence is the differentiation of the single layer of cells of the blastula into the two

primary *germ layers*. The process may be compared to forcing in one side of a hollow rubber ball. One side of the blastula becomes turned into the other, partially or completely obliterating the segmentation cavity. In this way two layers are formed, an outer *ectoderm* (*epiblast* of English embryologists) and an inner *entoderm* (*hypoblast*). The opening into the cavity of the entoderm is known as the *blastopore*, while the cavity itself, from the fact that it forms the digestive tract of the adult, is called the *archenteron*, while for similar reasons the embryo at this stage is termed the *gastrula* (Fig. 1 right). In eggs with unequal segmentation it is the larger cells which form the entoderm, and in this way the food yolk, to which they owe their size, is brought into the walls of the digestive tract. In eggs with meroblastic segmentation the phenomena of formation of the gastrula are greatly modified and are impossible of description in a few words. They can, however, be harmonized with the foregoing account.

The mouth of the gastrula (blastopore) may remain permanently open and form the mouth of the adult, or it may close in the middle, the ends remaining open as mouth and anus. Again only one end may remain open, this forming in some the mouth, in others the anus. Lastly the blastopore may close completely and either mouth or anus may be formed outside its line of closure. From this it is evident that it is important to recognize the limits of the blastopore in tracing resemblances between different groups of animals, and this necessity is increased when we recollect that the central nervous system arises around the blastopore.

In some Coelenterates and scattered members of other groups of animals the two layers, ectoderm and entoderm, may arise in a different way. On arrival at the stage of the blastula the inner ends of the cells which compose its walls become cut off from the outer ends, thus forming the two layers. While in this case the segmentation cavity becomes converted into the archenteron. This process is called *delamination* and is difficult to reconcile with the process described above.

In many Coelenterates and a few other imperfectly known forms, the adult animal does not progress beyond the two-layered stage and hence these are sometimes grouped as the *Diploblastica*, in contrast to the *Triploblastica*, in which a third layer is added. This additional germ layer is the *mesoderm* (mesoblast of the English). It arises either from the entoderm or from the line of junction between ectoderm and entoderm and extends into the space (remains of the segmentation cavity) between these two layers, making up, in most animals, by far the largest part of the adult body. It shows considerable differences in its method of origin even in one and the same animal, and is frequently subdivided by writers into *mesothelium* and *mesenchyme* by characters which need not be detailed here.

From these three (or four) germ layers all the structures of higher animals (metazoa) arise. The derivation of the various structures in man may be enumerated here.

Ectoderm.—External layer (epidermis) of skin, hair, nails, sweat and milk glands, brain, spinal cord, nerves, the sensory portions of ears, eyes, nose, etc., lining of mouth, enamel of teeth.

EMBRYOLOGY

Entoderm.—Lining of digestive tract (including its glands—liver, pancreas, etc.) of Eustachian tube, windpipe, lungs and lining of lungs not of notochord.

Mesothelium.—Lining of body cavity (peritoneum), pleura, and pericardium; all voluntary muscles of the body and muscles of the heart; internal reproductive and excretory organs.

Mesenchyme.—Deeper layers (derma) of skin, and of alimentary tract; tendons, fat, cartilage, bone, dentine of teeth; involuntary muscles with the exception of those of the heart; blood-vessels, blood, and lymph.

Space will not permit tracing the development of the various organs of all animals from

during this process from a spherical to a more elongate form.

On the dorsal surface, around the line of closure of the blastopore, the ectoderm becomes thickened, forming a *medullary plate*, broader in front. The edges of this plate gradually rise, roll inward toward each other and gradually convert the plate into a tube, from which later will develop the central nervous system. The broader anterior portion gives rise to the brain (Fig. 2), the rest to the spinal cord, while the lumen of the tube forms the canal of the cord as well as the cavities (ventricles) of the brain. Starting from this central system the nerves attain their outward growth later.

The eyes arise in large part from the brain, extending outward from it as hollow vesicles which grow laterally toward the ectoderm of the side of the head. Then the vesicle becomes folded into itself like a double cup, the inner wall of which gradually develops into the retina, while the optic nerve grows backward along the line of the stalk of the cup into the brain. The lens of the eye has its origin in the ectoderm of the side of the head opposite the outgrowing optic vesicle. This thickening increases, becomes folded

into a ball and becomes cut off from the rest to sink to its permanent position at the mouth of the optic cup. The essential or sensory part of the ear begins as a pit on the side of head behind the eye. This deepens and sinks inward to join the outgrowing auditory nerve. It later becomes closed and completely cut off from the skin and by a complicated process of folding becomes developed into the two chambers and the three semicircular canals of the adult, these corresponding in position and origin to those of man. (There are no middle and outer ears in the salamander.)

The entoderm, arising by the modified process of gastrulation, becomes more and more elongate with the lengthening of the embryo. Behind, the canal (archenteron) remains small (Fig. 2, *i*), the ventral wall being enormously thickened by the large amount of yolk present. In front the cavity enlarges to form the liver (*l*), while in front of this is a short portion which has to develop into pharynx, gullet, and stomach. As yet there is no mouth. This arises first as an inpushing of the ectoderm in front (*m*) which later breaks through into the pharynx. In the pharyngeal region paired pockets grow out right and left until they meet the ectoderm with which they fuse (*g*). Then at the bottom of each pocket an opening appears so that this region is in connection with the exterior. These openings are the gill slits. Similar gill pouches are formed in the embryos of all vertebrates, but in the higher groups (reptiles, birds, and mammals) they are transitory with the exception of the anterior which forms the middle ear (tympaenum) and Eustachian tube of the adult. Oesophagus and stomach develop later by elongation and differentiation of the region between the liver and pharynx, while the intestine arises from the part behind the liver outgrowth.

The mesoderm grows in as two double sheets

FIG. 2.—Diagrammatic long section of a salamander embryo. *a*, anus; *e*, place of outgrowth of eye; *fb*, fore-brain; *g*, gill slits extending outward from pharynx; *h*, heart in pericardium; *hb*, hind-brain; *l*, intestine; *l*, beginning of liver; *m*, thickening of ectoderm where mouth will form; *mb*, mid-brain; *n*, notochord; *s*, spinal cord; *va*, ventral aorta. Cut surface of entoderm dotted.

these germ layers, but later in this article a slight sketch of the processes as they occur in the vertebrates will be given.

From the stage in which the germ layers are formed some animals develop directly into the adult, while in others larval stages, differing markedly from the adults in appearance, are introduced. In some instances these larvæ are clearly adaptations to enable the young to begin its free life and its self-support as early as possible; in others they are indicative of the ancestry, representing, in the history of the individual, stages passed through in the development of the race. Larvæ are more abundant among marine than among fresh-water or terrestrial forms. See LARVA.

Development of Organs.—Space will permit the outlining of the development of organs from the germ layers in but one animal. For reasons of simplicity and of general interest the salamander has been selected as a type of the group of which man is a member.

The eggs of the salamander are laid in the spring, enclosed in a transparent jelly. They are fertilized after being laid, form polar globules, and undergo a total but unequal segmentation, a result of the large amount of food yolk present. The small segmentation cavity is consequently excentric in position. Since the segmentation cavity is small the gastrula cannot be formed in the typical way described above, but rather by a modified type of infolding, not easily described in a few words. The blastopore closes along what will eventually make the middle line of the back, the egg changing

EMBRYOLOGY

between the ectoderm and entoderm (Fig. 3, *m*), the space between the two layers being called the coelom (*c*). These mesodermal sheets extend on either side of the body from near the

FIG. 3.—Diagram of anterior part of amphibian embryo; *a*, alimentary canal; *c*, coelom or body cavity; *e*, entoderm; *m*, two layers of mesoderm; *n*, notochord; *s*, spinal cord.

tip of the head to the end of the tail. At first they are dorsal in position, but with increase in size the lower margins approach the mid-ventral line, where they finally fuse.

The dorsal portion of each mesoderm plate soon becomes cut up into a series of cubical blocks, the *myotomes*, each myotome containing a portion of the coelom. These myotomes are to furnish the voluntary muscles of the body. They finally separate completely from the rest of the mesoderm and begin to grow downward between the ectoderm and the lower part of the mesoderm until they extend to near the middle ventral line. During this process the inner wall of each myotome becomes transformed into muscle fibres and in this way plates of muscle (familiar to all in the flesh of a fish) arise. The muscles of the limbs arise as buds from a few myotomes in the regions where the limbs are to appear. With the outgrowth of the limb the buds extend into it and gradually become differentiated into the various muscles. The outer layer of the myotome is not transformed into muscle but gives rise to a connective tissue, the *cutis* or *derma*, which, together with the ectoderm (*epidermis*), forms the skin.

From the region just below the myotomes a second series of segments are formed which have for their most marked functions the formation of the excretory organs, and hence are called nephrotomes (*νεφροτὸν*, kidney). The history of these organs is too complex to be followed here. Suffice it to say that in the salamander as in all fish-like vertebrates (Ichthyopsida), there are two kidneys formed in succession, an anterior head-kidney (*pronephros*) and a posterior Wolffian body (*mesonephros*), the latter forming the functional kidney of the adult. In the higher vertebrates (reptiles, birds, and mammals) both pro- and mesonephros are formed in the embryo and these are replaced later by a third kidney (*metanephros*) which alone serves an excretory organ in the adult. The nephrotomes also give rise, directly or indirectly, to the ducts of the reproductive and excretory organs, while from the inner surfaces are budded off cells (mesenchyme)

which, among other functions, have to form the skeleton, mentioned below.

The lower portion of the mesoderm does not become divided as do the two upper regions. Its outer wall becomes applied to the muscles, while its inner covers the various viscera, thus forming the lining or *peritoneum* of the lower part of the coelom which is usually called the body cavity. The only division of this cavity in the lower vertebrates is by means of a transverse partition, the *septum transversum*, which separates an anterior *pericardium* containing the heart from the peritoneal cavity containing the other viscera. In the mammals a second partition, the *diaphragm*, occurs behind the first, marking off the pleural cavities, containing the lungs, from the rest of the peritoneal cavity.

The first skeletal structure to appear is the notochord, a rod of gelatinous tissue which arises in the middle dorsal line from the entoderm, becomes cut off from it and comes to lie between the digestive tract and the central nervous system (Figs. 2, 3 *n*). Behind, it extends to the tip of the tail, but in front it does not reach the tip of the head, but is terminated at a down-growth from the brain, the infundibulum. This rod is not jointed, but serves as a centre around which the vertebrae and the base of the posterior part of the skull arise.

The tissue for the vertebrae and the floor of the skull is furnished by the mesenchyme from the nephrotomes, the origin of which was alluded to above. This tissue gathers around the notochord and forms rings around it, the bodies of the vertebrae; while connected with each body is a plate on either side, the two plates meeting above the spinal cord and forming the *neural arch*. Extending outward between the muscle plates are the rudiments of the ribs. At first vertebrae and ribs are cartilaginous, but later the cartilage becomes replaced by bone. In the head region a cartilaginous skull arises in a somewhat similar way. This is very complex, but may be divided into a cranial and a visceral portion, the latter consisting of cartilage bars for the jaws and between the gill slits. In the cranium only that part which arises around the anterior extremity of the notochord can be compared to the vertebrae. This cartilaginous skull becomes converted into the bony skull of the adult, in part by direct conversion of the cartilages into bone, in part by the formation of additional bones (dermal bones) in the skin which unite with those of cartilaginous origin. The skeletons of the girdles and limbs are almost entirely of cartilage origin, only the coracoid arising as a dermal bone.

The circulatory system is very complicated and only a small part of its development can be outlined here. In the pharyngeal region the descending plates of mesoderm meet below the entoderm, enclosing between them a tube lined by cells of uncertain, though probably of entodermal origin. These cells form the lining of the heart (*endothelium*), while the walls of mesoderm later furnish the muscles of this organ. The coelom of this region becomes converted into the pericardial cavity.

At first this heart tube is straight, but since it grows faster than the pericardium it becomes twisted somewhat like the letter S and the auricle and ventricle develop out of the folds of the twist (Fig. 2, *h*), valves soon appearing

EMBRYOLOGY

between these chambers. Behind the heart the edges of the mesoderm are prevented from joining by the presence of the liver and hence there arise here two vessels which bring the blood from behind to the heart. In front of the heart is formed in a similar way a tube, the ventral aorta (Fig. 2 *va*), from which vessels (*aortic arches*) gradually grow upward around the pharynx in the tissue between the gill slits. These finally enter vessels above the pharynx which by their union form the dorsal aorta which runs backward above the alimentary tract to the tail. From this dorsal aorta vessels are given off at regular intervals which extend out laterally between the myotomes and serve to carry blood to these last.

From this comparatively simple arrangement the more complicated blood system of the adult is developed by the appearance of other vessels and the disappearance of some which are formed at first; the details of which must be sought in special works. One or two points have more interest and may be mentioned here. For various reasons it seems certain that in the early vertebrates there were formed six pairs of these aortic arches connecting the ventral and dorsal aortæ. In the salamander only the posterior four of these come to development, the anterior two on either side remaining rudimentary. In the development of the higher animals, as in man, there is the same formation of paired arches in the early embryo. Later in the history the fifth arch on either side is entirely lost, the sixth loses its connection with the dorsal aorta and sends its blood to the lungs, thus giving rise to the pulmonary arteries. Of the third pair that on the right side largely disappears, while that on the right persists as the "arch of the aorta" of human anatomy and alone carries blood to the dorsal aorta and the trunk. The anterior arches also lose their connection with the posterior dorsal trunks and give rise to the carotid arteries which carry blood to the head.

With this outline of the comparatively simple development of the salamander the more complicated features of the history of a higher vertebrate can better be understood. In many of their features these closely parallel the account just given. In the reptiles, birds, and mammals other features are added. Thus at an early stage there is formed an embryonic envelope which encloses the whole germ. In some mammals as in man this arises by a splitting of the ectoderm so that the embryo comes to lie in a cavity roofed in above by a delicate membrane, the *amnion*. In many other mammals, as in reptiles and birds, this amnion arises by an up-growth of ectoderm all around the embryo, these growths finally meeting and fusing above the embryo, thus finally enclosing an amniotic cavity similar to that in man.

In the salamander egg, the amount of food yolk is comparatively small. In the birds and reptiles it is enormous in amount. As a result the young reptile or bird appears as a small outgrowth on the surface of a large sphere of yolk. The presence of this causes the blood vessels described above as entering the heart from behind to extend down over the yolk, while other vessels extend to the same region from the dorsal aorta. By means of these a yolk circulation is set up and thus the yolk itself is gradually torn down and carried by the vessels

into the circulation and thus used in building up the body. Later this yolk circulation, lying beneath the egg shell, serves as a means of respiration, absorbing oxygen from the air and giving off the carbon dioxide produced by growth.

In most mammals the whole embryonic period (including the foetal stages) is passed inside the mother, a fact which has resulted in considerable modifications of the processes. Thus the egg has lost its food yolk and has a total, although irregular, segmentation. Larval organs have been lost, but the most remarkable changes are the provisions for furnishing nourishment to the growing embryo and the later foetus. These may be briefly summarized by saying that an outgrowth occurs at the hinder end of the alimentary canal, the *allantois*, which carries with it arteries and a vein. This allantois increases in size, extending outward into the amniotic cavity, and finally uniting with its outer wall, the chorion. From this union is developed that structure so characteristic of mammals, the *placenta*. This portion comes in contact with the walls of the maternal uterus, while from its outer surface are developed numerous small, thread-like outgrowths, the chorionic villi. These penetrate into the uterine walls, which in the meantime have become spongy through the great development of blood vessels, and from this union the placenta is formed. Blood (or rather its serum) passes by osmosis from the vessels of the uterus into the villi and thence by the allantoic vein to the embryo, while blood which has done its work in the embryo is carried back by the same course to the mother. It is to be noted that at no time is there a direct connection of the blood vessels of parent and off-spring, all transfer being osmotic.

With growth the placenta increases in size, while the stalk of the allantois and accessory structures remain small, and these smaller portions form the umbilical cord. The placenta varies in different animals, three chief types being recognized. In the cotyledonary, as in domestic cattle, the villi are gathered in numerous small patches or cotyledons; in the zonary type, as in dogs, the villi form a girdle or zone around the foetal envelopes; while in the discoidal condition (man), the villi occupy a disk-like area on the envelopes. At birth the young mammal is in position to breathe for itself and to take food into the alimentary canal and hence the placental structures are no longer of value. They are, therefore, cast out as the "afterbirth," carrying with them a part of the uterine lining.

The literature of embryology is very large and reference can be made to but a few manuals, which, however, have good bibliographies. A classic work is Balfour's 'Treatise on Embryology' (2 vols., London 1880-1), which includes all groups of animals. Most recent for invertebrates is the *Embryology of Korschelt and Heider* (translated in 4 volumes, 1900). For vertebrates the best text-books are Minot, 'Human Embryology' (1892), and Mark's translation of Hertwig's 'Embryology' (1892). A smaller, more recent and very clear work is McMurrich, 'Development of the Human Body' (1902). All of these, while emphasizing man in the titles, deal with other vertebrates.

J. S. KINGSLEY,
Professor of Zoology, Tuft's College.

Embury, Emma Catharine Manley, American writer: b. New York 1806; d. Brooklyn, N. Y., 10 Feb. 1863. She was married to Daniel Embury in 1828. Much of her work for periodicals was over the pen-name "Ianthé." Among her published works are: 'Guido and Other Poems' (1828); 'Female Education'; 'The Blind Girl, and Tales'; 'Love's Token Flowers' (1846); 'Poems' (1869).

Embury, Philip, Methodist clergyman: b. Ballygaran, Ireland, 21 Sept. 1729; d. Camden, N. Y., August 1775. He joined John Wesley's society and became a local preacher at Court-Matthew in 1758. Emigrating to New York in 1760, he began to preach in his own house in 1766, and two years later erected a chapel on the site of the present "Old John Street Church." Being a carpenter by trade, he worked on the building with his own hands and completed the pulpit, in which he preached the sermon of dedication 30 Oct. 1768. This was the first Methodist chapel of the New World, and he has been called "the founder of American Methodism." It was, however, at Camden, Washington County, N. Y., that he did his greatest work, forming there a congregation which grew into the flourishing and influential Troy Conference.

Em'den, Germany, town, in the province of Hanover, on the Ems, near where it discharges itself into the Dollart estuary. Emden has an excellent roadstead, and its harbor is connected with this by a canal admitting large vessels. The Dortmund-Ems and other canals connect it with the interior. Its export trade includes grain, dairy produce, cattle, tallow, wool, hides, etc.; and it imports coal, timber, wine, and colonial produce. A considerable number of vessels are built here annually; and the manufactures include leather, paper, wire ropes, bricks, soap, and tobacco. There are also oil-mills, breweries, and distilleries. Pop. (1900) 16,453.

Emelé, ā-mā-lā, Wilhelm, German painter: b. Buchen, Odenwald, 1830. He first adopted a military career but studied art with Dietz at Munich, and later at Antwerp and Paris. His canvases are noted for exactness of details, his subjects being military. He has lived in Vienna since 1861. Among his works are: 'Battle of Stockach'; 'Capture of Heidelberg Bridge in 1799' (1857); 'The Fight Near Aldenhoven' (1859); 'The Square of the Battle of Aspern' (1860); 'Capture of Camp Near Farmers'; 'Attack on the English by French Cuirassiers at Waterloo'; 'Battle of Wurzburg' (1867), his best work; 'The Archduke Charles at Battle of Neerwinden' (1872); 'Attack of the Bournern Division Near Elsasshausen'; 'Battle of Dijon'; 'Meeting of Patrols of Seventh and Fourteenth Corps, Prussian Army, Near Vesoul'; 'Headquarters of 14th Army Corps in Battle of Belfast'; 'Episode of Battle of Worth'; 'Victory of George II. over the French at Dettingen' (1879).

Emerald (O. Fr. *emeraude*, Gr. *σμάραγδος*), a gem of pure green color, often very rich and beautiful. It is a variety of the mineral beryl and is, therefore, a silicate of aluminum and glucinum (q.v.), its green color being due to the presence of a little chromium. It is usually found in nodules or in distinct six-sided prisms of the hexagonal system. It is a little harder than quartz, and has a specific gravity of about

2.69. It is not acted on by acids. Many of the most intensely colored and valuable emeralds that we are acquainted with were brought from Peru, the largest from Takowaja, in the Urals, a specimen of which is seen in the 6¾-pound stone at St. Petersburg. Most modern emeralds come from the Republic of Colombia, which quite supplies the current market. In the United States emerald crystals up to nine inches in length and of rich color have been found in Alexander County, N. C., while extensive mining in Mitchell County, N. C., has yielded beautiful gems and much so-called "emerald matrix." The rarity, rich color, brilliancy and hardness of emerald have made it one of the most highly prized of gems. "Oriental emerald" is green sapphire (q.v.), "lithia emerald" is hiddenite (q.v.), "Uralian emerald" is demantoid (q.v.), "Brazilian emerald" is tourmaline (q.v.). See also BERYL and GEMS.

Emerald Green, known also as **Schweinfurth** or **Paris Green**, and by a great number of other names, is one of the most beautiful green pigments. It appears to contain copper, arsenic, and acetic acid, and is usually regarded as an aceto-arsenite of copper. It is a crystalline powder, which becomes paler by grinding, is not affected by light and air, and is insoluble in water, but is decomposed by alkalis. It is used both as a water and as an oil color, and is used for tinting wall-papers, though with much less frequency since the danger of that practice has been discovered.

Emerald Isle, an epithet applied to Ireland, from the freshness and bright color of the verdure, produced by the abundant heat and moisture continually reaching it from the Atlantic. This epithet was first used by Dr. W. Drennan (1754-1820), in his poem entitled 'Erin.'

Emerald Wedding. See WEDDING ANNIVERSARIES.

Emerson, Charles Wesley, American educator: b. Pittsfield, Vt., 30 Nov. 1837. Studying law, medicine and theology, he was a clergyman for many years. He founded the Emerson College of Oratory, Boston (1880), and has since been its president, teaching oratory, physical culture and voice development.

Emerson, Edward Waldo, American physician and author: b. Massachusetts 1844. He is a son of Ralph Waldo Emerson (q.v.). He was graduated at Harvard College and Harvard Medical School, and is an instructor in anatomy at the Boston Museum of Fine Arts. He has published: 'Emerson in Concord' (1888); and an edition of the 'Correspondence of John Sterling and Ralph Waldo Emerson, with sketch of Sterling's Life.'

Emerson, Mrs. Ellen (RUSSELL), American author: b. New Sharon, Maine, 16 Jan. 1837. She was married to Edwin Emerson (1862). Her works are: 'Indian Myths' (1884); 'Masks, Heads, and Faces, with Considerations Respecting the Rise and Development of Art' (1891).

Emerson, George Barrell, American educator: b. Kennebunk, York County, Maine, 12 Sept. 1797; d. Newton, Mass., 14 March 1881. He was graduated at Harvard College (1817), and was the tutor in mathematics and natural philosophy there (1819-21). In 1823 he opened

EMERSON

a private school for girls in Boston, which he conducted until 1855, when he retired from professional life. He wrote the second part of the 'School and Schoolmaster,' of which the first part was written by Bishop Potter of Pennsylvania. He was appointed chairman of the commissioners for the zoological and botanical survey of Massachusetts, in which capacity he published a 'Report of the Trees and Shrubs Growing Naturally in the Forests of Massachusetts' (1846).

Emerson, Luther Orlando, American composer: b. Parsonsfield, Maine, 3 Aug. 1820. He studied music and later taught for eight years in Salem, Mass. He then served as organist and musical director in various churches in Massachusetts, and was the director of about 300 musical festivals and conventions. He has published: 'The Romberg Collection' (1853); 'The Golden Wreath' (1857); 'The Golden Harp' (1858); 'The Sabbath Harmony' (1860); 'The Heart of Judah' (1863); 'Jubilate' (1866); etc.

Emerson, Oliver Farrar, American educator: b. Traer, Iowa, 1860. He studied at Iowa College, taking a post-graduate course at Cornell University. After serving as superintendent and principal of schools in Grinnell and Muscatine, Iowa, he was principal of the Academy of Iowa College (1885-8); instructor in English (1889-91) Cornell University, and assistant professor of rhetoric and English philology in the same institution (1892-6), when he took the same chair in Western Reserve University. He is secretary of the American Dialect Society, and is a regular contributor to philological papers. He has published: 'History of the English Language' (1894); 'A Brief History of the English Language' (1896); an edition of 'Dr. Johnson's Rasselas' (1895); and 'Memoirs of the Life and Writings of Edward Gibbon' (1898).

Emerson, Ralph Waldo, American poet and philosopher: b. Boston 25 May 1803; d. Concord, Mass., 27 April 1882. He was the son of a Unitarian clergyman. He was graduated at Harvard in 1821, and for five years taught in a school. Having studied divinity he was ordained colleague of Rev. Henry Ware at the Second Unitarian Church in Boston in 1829, but in 1832 resigned his charge, announcing his unwillingness any longer to administer the rite of the Lord's Supper. In Dec. 1832 he sailed for Europe and remained there nearly a year, having had interviews with Carlyle, Coleridge, Wordsworth, and other eminent writers. On his return he began his career as a lecturer, in which capacity he acted for a long series of years, and became known throughout the whole of the United States. In 1835 he took up his permanent residence at Concord, Mass. In 1836 he published a small volume called 'Nature,' treating of freedom, beauty, and culture in relation to the outer world. He was one of the original editors and chief supporters of 'The Dial,' a magazine begun in 1840, and identified with the trend of thought known as "transcendentalism." Two volumes of his 'Essays' were published in 1841 and 1844, and his 'Poems' in 1846. His 'Miscellaneous Addresses' had been collected and published in England in 1844, and on visiting there in 1847 he was welcomed by a large circle of admirers. In 1850 he published 'Representative Men,' including portraits

of Plato, Shakespeare, Montaigne, Swedenborg, Napoleon, Goethe; in 1856, 'English Traits'; in 1860, 'The Conduct of Life'; in 1869, 'May Day and Other Poems,' and 'Society and Solitude'; in 1871, 'Parnassus,' a compilation of poems; in 1876, 'Letters and Social Aims'; in 1893, 'Natural History of Intellect and Other Papers' appeared. He was twice married. He took but little active part in public life, but was always ready to lend his voice on behalf of any important movement. Though sometimes looked upon as a philosopher he was more of a poet and literary man than a systematic teacher, his writings being rather more suggestive of thought than directly didactic. Some of his essays, it has been remarked, seem "merely accidental collections of loose leaves from a note-book." Consult: Cooke, G. W., 'Ralph Waldo Emerson: Life, Writings, and Philosophy' (1882); Conway, 'Emerson at Home and Abroad' (1882); Ireland, 'Ralph Waldo Emerson: a Biographical Sketch' (1882); Holmes, O. W., 'Ralph Waldo Emerson' (1885); Cabot, 'A Memoir of Ralph Waldo Emerson' (1887); Emerson, E. W., 'Emerson in Concord' (1889); Benton, 'Emerson as a Poet' (1889); Chapman, J. J., 'Emerson and Other Essays' (1898); Woodberry, 'Life of Emerson'; Sanborn, 'Emerson.'

Emerson as Seer.* Emerson was not a logician or reasoner, and not a rhetorician, in the common sense. He was a poet, who wrote chiefly in prose, but also in verse. His verse was usually rough, but sometimes finished and melodious; it was always extraordinarily concise and expressive. During his engagement to the lady who became his second wife, he wrote thus to her: "I am born a poet—of a low class, without doubt, yet a poet; that is my nature and vocation. My singing, be sure, is very husky, and is, for the most part, in prose. Still, I am a poet in the sense of a perceiver and dear lover of the harmonies that are in the soul and in matter, and specially of the correspondences between these and those." This husky poet had his living to get. His occupations in life were those of the teacher, minister, lecturer, and author. He was a teacher at various times between 1818 and 1826, but he never liked teaching; a preacher at intervals from 1826 to 1847; but a settled minister only from 1829 to 1832. His career as a lecturer began in the autumn of 1833, and his first book, 'Nature,' was published in 1836, when he was 33 years old. His lectures for money were given as a rule during the winter and early spring, and for 30 years the traveling he was obliged to do in search of audiences was often extremely fatiguing and not without serious hardships and exposures. These occupations usually gave him an income sufficient for his simple wants; but there were times when outgo exceeded income. The little property his first wife left him (\$1,200 a year) relieved him from serious pecuniary anxiety by 1834, although it did not relieve him from earning by his own labor the livelihood of his family. In 1834 he went to live in Concord where his grandfather had been the minister at the time of the Revolution, and in 1835 he bought the house and grounds there which were his home for the rest of his days. Before settling in Concord, he had

*

RALPH WALDO EMERSON.

*

EMERSON

spent one winter and spring (1826-7) in the Southern States, and seven months of 1833 in Europe. Both of these absences were necessitated by the state of his health, which was precarious during his young manhood. With these exceptions, he had lived in Boston or its immediate neighborhood, until he settled in Concord. His progenitors on both sides were chiefly New England ministers. His formal education was received in the Boston Latin School and Harvard College, and was therefore purely local. How narrow and provincial seems his experience of life! A little city, an isolated society, a country village! Yet through books, and through intercourse with intelligent persons, he was really "set in a large place." The proof of this largeness, and of the keenness of his mental and moral vision, is that, in regard to some of the chief concerns of mankind, he was a seer and a fore-seer. This prophetic quality of his I hope to demonstrate in three great fields of thought—education, social organization, and religion.

Although a prophet and inspirer of reform, Emerson was not a reformer. He was but a halting supporter of the reforms of his day; and the eager experimenters and combatants in actual reforms found him a disappointing sort of sympathizer. His visions were far-reaching, his doctrines often radical, and his exhortations fervid; but when it came to action, particularly to habitual action, he was surprisingly conservative. With an exquisite candor and a gentle resolution of rarest quality he broke his strong ties to the Second Church of Boston before he was 30 years old, abandoning the profession for which he had been trained, and which, in many of its aspects, he honored and enjoyed; yet he attended church on Sundays all his life with uncommon regularity. He refused to conduct public prayer, and had many things to say against it; but when he was an overseer of Harvard College, he twice voted to maintain the traditional policy of compelling all the students to attend morning prayers, in spite of the fact that a large majority of the faculty urgently advocated abandoning that policy. He manifested a good deal of theoretical sympathy with the community experiments at Brook Farm and Fruitlands; but he declined to take part in them himself. He was intimate with many of the leading abolitionists, but no one has described more vividly their grave intellectual and social defects. He laid down principles which, when applied, would inevitably lead to progress and reform; but he took little part in the imperfect step-by-step process of actual reforming. He probably would have been an ineffective worker in any field of reform; and, at any rate, strenuous labor on applications of his philosophy would have prevented him from maintaining the flow of his philosophic and prophetic visions. The work of giving practical effect to his thought was left for other men to do—indeed for generations of other serviceable men, who, filled with his ideals, will slowly work them out into institutions, customs, and other practical values.

When we think of Emerson as a prophet, we at once become interested in the dates at which he uttered certain doctrines, or wrote certain pregnant sentences; but just here the inquirer meets a serious difficulty. He can sometimes ascertain that a given doctrine or sentence was published at a given date; but he may be quite

unable to ascertain how much earlier the doctrine was really formulated, or the sentence written. Emerson has been dead 21 years; and it is 30 years since he wrote anything new; but his whole philosophy of life was developed by the time he was 40 years old, and it may be doubted if he wrote anything after 1843, the germinal expression of which may not be found in his journals, sermons, or lectures written before that date. If, therefore, we find in the accepted thought or established institutions of to-day recent developments of principles and maxims laid down by Emerson, we may fairly say that his thought outran his times certainly by one, and probably by two generations of men.

I take up now the prophetic teachings of Emerson with regard to education. In the first place, he saw, with a clearness to which very few people have yet attained, the fundamental necessity of the school as the best civilizing agency, after steady labor, and the only sure means of permanent and progressive reform. He says outright: "We shall one day learn to supersede politics by education. What we call our root-and-branch reforms, of slavery, war, gambling, intemperance, is only medicating the symptoms. We must begin higher up—namely, in education." He taught that if we hope to reform mankind, we must begin not with adults, but with children: we must begin at school. There are some signs that this doctrine has now at last entered the minds of the so-called practical men. The Cubans are to be raised in the scale of civilization and public happiness; so both they and we think they must have more and better schools. The Filipinos, too, are to be developed after the American fashion; so we send them a thousand teachers of English. The Southern States are to be rescued from the persistent poison of slavery; and, after 40 years of failure with political methods, we at last accept Emerson's doctrine, and say: "We must begin earlier—at school." The city slums are to be redeemed; and the scientific charity workers find the best way is to get the children into kindergartens and manual training schools.

Since the Civil War, a whole generation of educational administrators has been steadily at work developing what is called the elective system in the institutions of education which deal with the ages above 12. It has been a slow, step-by-step process, carried on against much active opposition and more sluggish obstruction. The system is a method of educational organization which recognizes the immense expansion of knowledge during the 19th century, and takes account of the needs and capacities of the individual child and youth. Now, Emerson laid down in plain terms the fundamental doctrines on which this elective system rests. He taught that the one prudence in life is concentration; the one evil, dissipation. He said: "You must elect your work: you shall take what your brain can, and drop all the rest." To this exhortation he added the educational reason for it—only by concentration can the youth arrive at the stage of doing something with his knowledge, or get beyond the stage of absorbing and arrive at the capacity for producing. As Emerson puts it, "Only so can that amount of vital force accumulate which can make the step from knowing to doing." The educational institutions of to-day have not yet fully appreciated this all-important step from

EMERSON

knowing to doing. They are only beginning to perceive that, all along the course of education, the child and the youth should be doing something as well as learning something; should be stimulated and trained by achievement; should be constantly encouraged to take the step beyond seeing and memorizing to doing—the step, as Emerson says, “out of a chalk circle of imbecility into fruitfulness.” Emerson carried this doctrine right on into mature life. He taught that nature arms each man with some faculty, large or small, which enables him to do easily some feat impossible to any other, and thus makes him necessary to society; and that this faculty should determine the man's career. The advocates of the elective system have insisted that its results were advantageous for society as a whole, as well as for the individual. Emerson put this argument in a nutshell, at least 50 years ago: “Society can never prosper, but must always be bankrupt, until every man does that which he was created to do.”

Education used to be given almost exclusively through books. In recent years there has come in another sort of education through tools, machines, gardens, drawings, casts, and pictures. Manual training, shop-work, sloyd, and gardening have come into use for the school ages; the teaching of trades has been admitted to some public school systems; and, in general, the use of the hands and eyes in productive labor has been recognized as having good educational effects. The education of men by manual labor was a favorite doctrine with Emerson. He had fully developed it as early as 1837, and he frequently recurred to it afterward. In December of that year in a course of lectures on ‘Human Culture,’ he devoted one lecture to ‘The Hands.’ He saw clearly that manual labor might be made to develop not only good mental qualities, but good moral qualities. To-day, it is frequently necessary for practical teachers, who are urging measures of improvement, to point this out, and to say, just as Emerson said two generations ago, that any falseness in mechanical work immediately appears; that a teacher can judge of the moral quality of each boy in the class before him better and sooner from manual work than from book-work. Emerson taught that manual labor is the study of the external world; that the use of manual labor never grows obsolete, and is inapplicable to no person. He said explicitly, “A man should have a farm or a mechanical craft for his culture”; that there is not only health, but education in garden work; that when a man gets sugar, hominy, cotton, buckets, crockery ware, and letter paper by simply signing his name to a check, it is the producers and carriers of these articles that have got the education they yield, he only the commodity; and that labor is God's education. This was Emerson's doctrine more than 60 years ago. It is only 10 years since the Mechanic Arts High School was opened in Boston.

We are all of us aware that within the last 20 years there has been a determined movement of the American people toward the cultivation of art, toward the public provision of objects which open the sense of beauty and increase public enjoyment. It is curious to see how literally Emerson prophesied the actual direction of these efforts:

On the city's paved street
Plant gardens lined with lilac sweet;

Let spouting fountains cool the air,
Singing in the sun-baked square;
Let statue, picture, park, and hall,
Ballad, flag, and festival
The past restore, the day adorn,
And make to-morrow a new morn!

We have introduced into our schools, of late years, lessons in drawing, modeling, and designing,—not sufficiently, but in a promising and hopeful way. Emerson taught that it is the office of art to educate the perception of beauty; and he precisely describes one of the most recent of the new tendencies in American education and social life, when he says: “Beauty must come back to the useful arts, and the distinction between the fine and the useful arts be forgotten.” That sentence is the inspiration of one of the most recent of the efforts to improve the arts and crafts, and to restore to society the artistic craftsman. But how slow the institutional realization of this ideal of art education! We are still struggling in our elementary and secondary schools to get a reasonable amount of instruction in drawing and music, and to transfer from other subjects a fair allotment of time to these invaluable elements of true culture. They speak the universal language. Yet the ultimate object of art in education is to teach men to see nature to be beautiful and at the same time useful; beautiful, because alive and reproductive; useful, while symmetrical and fair. Take up to-day the last essays on education, the last book on landscape architecture, or the freshest teachings of the principles of design, and you will find them penetrated with Emerson's doctrine of art as teacher of mankind. Emerson insists again and again that true culture must open the sense of beauty; that “a man is a beggar who only lives to the useful.” It will probably require several generations yet to induce the American people to accept his doctrine that all moments and objects can be embellished, and that repose in energy, cheerfulness, and serenity are the “end of culture and success enough.”

It has been clearly perceived of late that a leading object in education is the cultivation of fine manners. On this point the teachings of Emerson are fundamental; but the American institutions of education are only beginning to appreciate their significance. He teaches that genius or love invents fine manners, “which the baron and the baroness copy very fast, and by the advantage of a palace, better the instruction. They stereotype the lesson they have learned into a mode.” There is much in that phrase, “by the advantage of a palace.” For generations, American institutions of education were content with the humblest sort of shelters, with plain wooden huts and brick barracks, and unkempt grounds about the buildings. They are only lately beginning to acquire fine buildings with pleasing surroundings; that is, they are just beginning to carry into practice Emerson's wisdom of 60 years ago. The American cities are beginning to build handsome houses for their high schools. Columbia University builds a noble temple for its library. The graduates and friends of Harvard like to provide her with a handsome fence round the yard, with a fair array of shrubs within the fence, with a handsome stadium instead of shabby, wooden seats round the football gridiron, and to take steps for securing in the future broad connections between the grounds of the university and the Cambridge parks by the river. They are just now carrying

1. Home of Emerson at Concord, Mass.

2. Library in the Emerson Home.

EMERSON

into practice Emerson's teaching; by the advantage of a palace they mean to better Harvard's instruction in manners. They are accepting his doctrine that "manners make the fortune of the ambitious youth; that for the most part his manners marry him, and, for the most part, he marries manners. When we think what keys they are, and to what secrets; what high lessons, and inspiring tokens of character they convey, and what divination is required in us for the reading of this fine telegraph,—we see what range the subject has, and what relations to convenience, power, and beauty."

In Emerson's early days there was nothing in our schools and colleges which at all corresponded to what we now know too much about under the name of athletic sports. The elaborate organization of these sports is a development of the last 30 years in our schools and colleges; but I find in Emerson the true reason for the athletic cult, given a generation before it existed among us. Your boy "hates the grammar and Gradus, and loves guns, fishing-rods, horses, and boats. Well, the boy is right, and you are not fit to direct his bringing-up, if your theory leaves out his gymnastic training. . . . Football, cricket, archery, swimming, skating, climbing, fencing, riding are lessons in the art of power, which it is his main business to learn. . . . Besides, the gun, fishing-rod, boat, and horse constitute, among all who use them, secret free-masonries." We shall never find a completer justification of athletic sports than that.

In his memorable address on 'The American Scholar,' which was given at Cambridge in 1837, Emerson pointed out that the function of the scholar should include creative action, or, as we call it in these days, research, or the search for new truth. He says: "The soul active . . . utters truth, or creates. . . . In its essence it is progressive. The book, the college, the school of art, the institution of any kind, stop with some past utterance of genius. . . . They look backward and not forward. But genius looks forward. Man hopes: genius creates. Whatever talents may be, if the man create not, the pure efflux of the Deity is not his;—cinders and smoke there may be, but not yet flame." And more explicitly still, he says: "Colleges have their indispensable office—to teach elements. But they can only highly serve us when they aim not to drill, but to create." When Emerson wrote this passage, the spirit of research, or discovery, or creation had not yet breathed life into the higher institutions of learning in our country; and to-day they have much to do and to acquire before they will conform to Emerson's ideal.

There are innumerable details in which Emerson anticipated the educational experiences of later generations. I can cite but two of them. He taught that each age must write its own books; "or rather, each generation for the next succeeding. The books of an older period will not fit this." How true that is in our own day, when 80,000 new books come from the press of the civilized world in a single year! Witness the incessant re-making or re-casting of the books of the preceding generation! Emerson himself has gone into thousands of books in which his name is never mentioned. Even history has to be re-written every few years, the long-surviving histories being rather monuments

of style and method than accepted treasuries of facts. Again, contrary to the prevailing impression that the press has, in large measure, stripped eloquence of its former influence, Emerson taught that "if there ever was a country where eloquence was a power, it is the United States." He included under eloquence the useful speech, all sorts of political persuasion in the great arena of the Republic, and the lessons of science, art, and religion which should be "brought home to the instant practice of thirty millions of people," now become eighty. The colleges and universities have now answered in the affirmative Emerson's question, "Is it not worth the ambition of every generous youth to train and arm his mind with all the resources of knowledge, of method, of grace, and of character to serve such a constituency?" But then Emerson's definition of eloquence is simple, and foretells the practice of to-day rather than describes the practice of Webster, Everett, Choate, and Winthrop, his contemporaries: "Know your fact; hug your fact. For the essential thing is heat, and heat comes of sincerity. . . . Eloquence is the power to translate a truth into language perfectly intelligible to the person to whom you speak."

I turn next to some examples of Emerson's anticipation of social conditions, visible to him as seer in his own day, and since become plain to the sight of the ordinary millions. When he accumulated in his journals the original materials of his essay on Worship, there were no large cities in the United States in the present sense of that term. The great experiment of democracy was not far advanced, and had not developed many of its sins and dangers; yet how justly he presented them in the following description: "In our large cities, the population is godless, materialized—no bond, no fellow-feeling, no enthusiasm. These are not men, but hungers, thirsts, fevers, and appetites walking. How is it people manage to live on, so aimless as they are? . . . There is faith in chemistry, in meat and wine, in wealth, in machinery, in the steam-engine, galvanic battery, turbine wheels, sewing-machines, and in public opinion, but not in divine causes."

In Emerson's day, luxury in the present sense had hardly been developed in our country; but he foresaw its coming, and its insidious destructiveness. "We spend our incomes for paint and paper, for a hundred trifles, I know not what, and not for the things of a man. Our expense is almost all for conformity. It is for cake that we run in debt; it is not the intellect, not the heart, not beauty, not worship, that costs us so much. Why needs any man be rich? Why must he have horses, fine garments, handsome apartments, access to public houses and places of amusement? Only for want of thought. . . . We are first thoughtless, and then find that we are moneyless. We are first sensual and then must be rich." He foresaw the young man's state of mind to-day about marriage—I must have money before I can marry; and deals with it thus: "Give us wealth and the home shall exist. But that is a very imperfect and inglorious solution of the problem, and therefore no solution. Give us wealth! You ask too much. Few have wealth; but all must have a home. Men are not born rich; in getting wealth the man is generally sacrificed, and often is sacrificed without acquiring wealth at last."

EMERSON

We have come to understand by experience that the opinion of masses of men is a formidable power which can be made safe and useful. In earlier days this massed opinion was either despised or dreaded; and it is dreadful if either confined or misdirected. Emerson compares it to steam. Studied, economized, and directed, steam has become the power by which all great labors are done. Like steam is the opinion of political masses! If crushed by castles, armies, and police, dangerously explosive; but if furnished with schools and the ballot, developing "the most harmless and energetic form of a state." His eyes were wide open to some of the evil intellectual effects of democracy. The individual is too apt to wear the time-worn yoke of the multitude's opinions. No multiplying of contemptible units can produce an admirable mass. "If I see nothing to admire in a unit, shall I admire a million units?" The habit of submitting to majority rule cultivates individual subservience. He pointed out two generations ago that the action of violent political parties in a democracy might provide for the individual citizen a systematic training in moral cowardice.

It is interesting, at the stage of industrial warfare which the world has now reached, to observe how Emerson, 60 years ago, discerned clearly the absurdity of paying all sorts of service at one rate, now a favorite notion with some labor unions. He points out that even when all labor is temporarily paid at one rate, differences in possessions will instantly arise: "In one hand the dime became an eagle as it fell, and in another hand a copper cent. For the whole value of the dime is in knowing what to do with it." Emerson was never deceived by a specious philanthropy, or by claims of equality which find no support in the nature of things. He was a true democrat, but still could say: "I think I see place and duties for a nobleman in every society; but it is not to drink wine and ride in a fine coach, but to guide and adorn life for the multitude by forethought, by elegant studies, by perseverance, self-devotion, and the remembrance of the humble old friend — by making his life secretly beautiful." How fine a picture of the democratic nobility is that!

In his lecture on 'Man the Reformer,' which was read before the Mechanics' Apprentices' Association in Boston Jan. 1841, Emerson described in the clearest manner the approaching strife between laborers and employers, between poor and rich, and pointed out the cause of this strife in the selfishness, unkindness, and mutual distrust which ran through the community. He also described, with perfect precision, the only ultimate remedy — namely, the sentiment of love. "Love would put a new face on this weary old world in which we dwell as pagans and enemies too long. . . . The virtue of this principle in human society in application to great interests is obsolete and forgotten. But one day all men will be lovers; and every calamity will be dissolved in the universal sunshine." It is more than 60 years since those words were uttered, and in those years society has had large experience of industrial and social strife, of its causes and consequences, and of many attempts to remedy or soften it; but all this experience only goes to show that there is but one remedy for these ills. It is to be found in kindness, good fellowship, and the affections. In Emerson's words, "We must be lovers, and at once the

impossible becomes possible." The world will wait long for this remedy, but there is no other.

Like every real seer and prophet whose testimony is recorded, Emerson had intense sympathy with the poor, laborious, dumb masses of mankind, and being a wide reader in history and biography, he early arrived at the conviction that history needed to be written in a new manner. It was long before Green's History of the English People that Emerson wrote: "Hence it happens that the whole interest of history lies in the fortunes of the poor." In recent years this view of history has come to prevail, and we are given the stories of institutions, industries, commerce, crafts, arts, and beliefs, instead of the stories of dynasties and wars. For Emerson it is always feats of liberty and wit which make epochs of history. Commerce is civilizing because "the power which the sea requires in the sailor makes a man of him very fast." The invention of a house, safe against wild animals, frost, and heat, gives play to the finer faculties, and introduces art, manners, and social delights. The discovery of the post-office is a fine metre of civilization. The sea-going steamer marks an epoch; the subjection of electricity to take messages and turn wheels marks another. But, after all, the vital stages of human progress are marked by steps toward personal, individual freedom. The love of liberty was Emerson's fundamental passion:

For He that ruleth high and wise,
Nor pauseth in His plan,
Will take the sun out of the skies
Ere freedom out of man.

The new National League of Independent Workmen of America has very appropriately taken its motto from Emerson:

For what avail the plough or sail
Or land or life, if freedom fail?

The sympathetic reader of Emerson comes often upon passages written long ago which are positively startling in their anticipation of sentiments common to-day and apparently awakened by very recent events. One would suppose that the following passage was written yesterday. It was written 56 years ago. "And so, gentlemen, I feel in regard to this aged England, with the possessions, honors, and trophies, and also with the infirmities of a thousand years gathering around her, irretrievably committed as she now is to many old customs which cannot be suddenly changed; pressed upon by the transitions of trade, and new and all incalculable modes, fabrics, arts, machines, and competing populations — I see her not dispirited, not weak, but well remembering that she has seen dark days before; indeed, with a kind of instinct that she sees a little better in a cloudy day, and that in storm of battle and calamity, she has a secret vigor and a pulse like a cannon."

Before the Civil War the Jew had no such place in society as he holds to-day. He was by no means so familiar to Americans as he is now. Emerson speaks twice of the Jew in his essay on 'Fate,' in terms precisely similar to those we commonly hear to-day: "We see how much will have been expended to extinguish the Jew, in vain. . . . The sufferance which is the badge of the Jew has made him in these days the ruler of the rulers of the earth." Those keen observations were made certainly more than 40 years ago, and probably more than 50.

EMERSON

Landscape architecture is not yet an established profession among us, in spite of the achievements of Downing, Cleveland, and Olmsted and their disciples; yet much has been accomplished within the last 25 years to realize the predictions on this subject made by Emerson in his lecture on 'The Young American.' He pointed out in that lecture that the beautiful gardens of Europe are unknown among us, but might be easily imitated here, and said that the landscape art "is the fine art which is left for us. . . . The whole force of all arts goes to facilitate the decoration of lands and dwellings. . . . I look on such improvement as directly tending to endear the land to the inhabitant." The following sentence might have been written yesterday, so consistent is it with the thought of to-day: "Whatever events in progress shall go to disgust men with cities, and infuse into them the passion for country life and country pleasures, will render a service to the whole face of this continent, and will further the most poetic of all the occupations of real life, the bringing out by art the native but hidden graces of the landscape." In regard to books, pictures, statues, collections in natural history, and all such refining objects of nature and art, which heretofore only the opulent could enjoy, Emerson pointed out that in America the public should provide these means of culture and inspiration for every citizen. He thus anticipated the present ownership by cities, or by endowed trustees, of parks, gardens, and museums of art or science, as well as of baths and orchestras. Of music in particular he said: "I think sometimes could I only have music on my own terms; could I . . . know where I could go whenever I wished the ablution and inundation of musical waves—that were a bath and a medicine." It has been a long road from that sentence, written probably in the forties, to the Symphony Orchestra in this hall and to the new singing classes on the East Side of New York.

For those of us who have attended to the outburst of novels and treatises on humble or squalid life, to the copious discussions on child-study, to the masses of slum literature, and to the numerous writings on home economics, how true to-day seems the following sentence written in 1837: "The literature of the poor, the feelings of the child, the philosophy of the street, the meaning of household life are the topics of the time."

I pass now to the last of the three topics which time permits me to discuss—Emerson's religion. In no field of thought was Emerson more prophetic, more truly a prophet of coming states of human opinion, than in religion. In the first place, he taught that religion is absolutely natural—not supernatural, but natural:

Out from the heart of Nature rolled
The burdens of the Bible old.

He believed that revelation is natural and continuous, and that in all ages prophets are born. Those souls out of time proclaim truth, which may be momentarily received with reverence, but is nevertheless quickly dragged down into some savage interpretation which by and by a new prophet will purge away. He believed that man is guided by the same power that guides beast and flower. "The selfsame power that brought me here, brought you," he says to

beautiful Rhodora. For him worship is the attitude of those "who see that against all appearances the nature of things works for truth and right forever." He saw good not only in what we call beauty, grace, and light, but in what we call foul and ugly. For him a sky-born music sounds "from all that's fair; from all that's foul":

'Tis not in the high stars alone,
Nor in the cups of budding flowers,
Nor in the redbreast's mellow tone,
Nor in the bow that smiles in showers,
But in the mud and scum of things
There always, always something sings.

The universe was ever new and fresh in his eyes, not spent, or fallen, or degraded, but eternally tending upward:—

No ray is dimmed, no atom worn,
My oldest force is good as new,
And the fresh rose on yonder thorn
Gives back the bending heavens in dew.

When we come to his interpretation of historical Christianity, we find that in his view the life and works of Jesus fell entirely within the field of human experience. He sees in the deification of Jesus an evidence of lack of faith in the infinitude of the individual human soul. He sees in every gleam of human virtue not only the presence of God, but some atom of his nature. As a preacher he had no tone of authority. A true non-conformist himself, he had no desire to impose his views on anybody. Religious truth, like all other truth, was to his thought an unrolling picture, not a deposit made once for all in some sacred vessel. When people who were sure they had drained that vessel, and assimilated its contents, attacked him, he was irresponsive or impassive, and yielded to them no juicy thought; so they pronounced him dry or empty. Yet all of Emerson's religious teaching led straight to God,—not to a withdrawn creator, or anthropomorphic judge or king, but to the all-informing, all-sustaining soul of the universe.

It was a prophetic quality of Emerson's religious teaching that he sought to obliterate the distinction between secular and sacred. For him all things were sacred, just as the universe was religious. We see an interesting fruition of Emerson's sowing in the nature of the means of influence, which organized churches and devout people have, in these later days, been compelled to resort to. Thus the various religious denominations keep their hold on their natural constituency quite as much by schools, gymnasiums, hospitals, entertainments, and social parades as by their rites and preaching. They maintain in city slums "settlements," which use secular rather than the so-called sacred methods. The fight against drunkenness, and the sexual vice and crimes of violence which follow in its train, is most successfully maintained by eliminating its physical causes and providing mechanical and social protections.

For Emerson inspiration meant not the rare conveyance of supernatural power to an individual, but the constant incoming into each man of the "divine soul which also inspires all men." He believed in the worth of the present hour:

Future or Past no richer secret folds,
Oh friendless Present! than thy bosom holds.

He believed that the spiritual force of human character imaged the divine:—

The sun set, but set not his hope:
Stars rose; his faith was earlier up:

EMERSON

Fixed on the enormous galaxy,
Deeper and older seemed his eye.

Yet man is not an order of nature, but a stupendous antagonism, because he chooses and acts in his soul. "So far as a man thinks, he is free." It is interesting to-day, after all the long discussion of the doctrine of evolution, to see how the much earlier conceptions of Emerson match the thoughts of the latest exponents of the philosophic results of evolution.

The present generation of scholars and ministers have been passing through an important crisis in regard to the sacred books of Judaism and Christianity. All the features of the contest over "the higher criticism" are foretold by Emerson in 'The American Scholar.' "The poet chanting was felt to be a divine man; henceforth the chant is divine also. The writer was a just and wise spirit; henceforth it is settled the book is perfect. Colleges are built on it; books are written on it. . . . Instantly the book becomes noxious; the guide is a tyrant." This is exactly what has happened to Protestantism, which substituted for infallible Pope and Church an infallible Book; and this is precisely the evil from which modern scholarship is delivering the world.

In religion Emerson was only a 19th-century non-conformist, instead of a 15th- or 17th-century one. It was a fundamental article in his creed that, although conformity is the virtue in most request, "Whoso would be a man must be a non-conformist." In the midst of increasing luxury, and of that easy-going, unbelieving conformity which is itself a form of luxury, Boston, the birthplace of Emerson, may well remember with honor the generations of non-conformists who made her, and created the intellectual and moral climate in which Emerson grew up. Inevitably, to conformists and to persons who still accept doctrines and opinions which he rejected, he seems presumptuous and consequential. In recent days we have even seen the word "insolent" applied to this quietest and most retiring of seers. But have not all prophets and ethical teachers had something of this aspect to their conservative contemporaries? We hardly expect the messages of prophets to be welcome; they imply too much dissatisfaction with the present.

The essence of Emerson's teaching concerning man's nature is compressed into the famous verse:

So nigh is grandeur to our dust,
So near is God to man,
When Duty whispers low, Thou must,
The youth replies, I can.

The cynic or the fall-of-man theologian replies — "Grandeur indeed, say rather squalor and shame." To this ancient pessimism Emerson makes answer with a hard question — "We grant that human life is mean, but how did we find out that it was mean?" To this question no straight answer has been found, the common answer running in a circle. It is hard indeed to conceive of a measure which will measure depths but not heights; and besides, every measure implies a standard.

I have endeavored to set before you some of the practical results of Emerson's visions and intuitions, because, though quite unfit to expound his philosophical views, I am capable of appreciating some of the many instances in

which his words have come true in the practical experience of my own generation. My own work has been a contribution to the prosaic, concrete work of building, brick by brick, the new walls of old American institutions of education. As a young man I found the writings of Emerson unattractive, and not seldom unintelligible. I was concerned with physical science, and with routine teaching and discipline; and Emerson's thinking seemed to me speculative and visionary. In regard to religious belief, I was brought up in the old-fashioned Unitarian conservatism of Boston, which was rudely shocked by Emerson's excursions beyond its well-fenced precincts. But when I had got at what proved to be my lifework for education, I discovered in Emerson's poems and essays all the fundamental motives and principles of my own hourly struggle against educational routine and tradition, and against the prevailing notions of discipline for the young. I cannot refuse the opportunity to point out how many of the sober, practical undertakings of to-day have been anticipated in all their principles by this solitary, shrewd, independent thinker, who, in an inconsecutive and almost ejaculatory way, wrought out many sentences and verses which will travel far down the generations. We know a good deal about the intellectual ancestors and inspirers of Emerson, and we are sure that he drank deep at many springs of idealism and poetry. Plato, Confucius, Shakespeare, and Milton were of his teachers; Oken, Lamarck, and Lyell lent him their scientific theories; and Channing stirred the residuum which came down to him through his forbears from Luther, Calvin, and Edwards. All these materials he transmuted and molded into lessons which have his own individual quality and bear his stamp. The precise limits of his originality are indeterminable, and inquiry into them would be unprofitable. In all probability the case would prove to be much the same with most of the men that the world has named prophets, if we knew as much of their mental history as we know of Emerson's. With regard to the Semitic prophets and seers, it is reasonable to expect that as Semitic exploration and discovery advance, the world will learn much about the historical and poetical sources of their inspiration. Then the Jewish and Christian peoples may come nearer than they do now to Emerson's conceptions of inspiration and worship, of the naturalness of revelation and religion, and of the infinite capacities of man. Meantime, it is an indisputable fact that Emerson's thought has proved to be consonant with the most progressive and fruitful thinking and acting of two generations since his working time. This fact, and the sweetness, fragrance, and loftiness of his spirit, prophesy for him an enduring power in the hearts and lives of spiritually minded men.

CHARLES W. ELIOT,
President of Harvard University.

Emerson, Canada, town, in Provencher County, province of Manitoba, on the Red River, at the terminus of branches of the Great N., and Canadian P. R.R.'s, and on the boundary between the United States and Canada. It is situated in one of the greatest wheat-growing sections of the world. Pop. 1,023.
